Research regarding privacy disclosure behaviors generally falls into one of two approaches. The first takes the side of the e-commerce company that would like as much information from its customers and potential customers as it can legally acquire, since such personalized information is highly valuable to for marketing and other business applications (Chellappa and Sin 2005; Lu et al. 2004; Xu et al. 2011). Furthermore, for e-commerce companies to gain revenues, their customers must generally supply at least a minimal amount of personal information (e.g., credit card or shipping information) in order to complete a transaction. Thus, this body of research investigates ways to mitigate privacy concerns so as to facilitate as much sharing of private information by the consumer as possible.

For example, Chellappa and Sin (2005) studied the likelihood of users to supply personal information in exchange for personalized browsing experiences, and trust building factors were proposed to mitigate users' privacy concerns. Lu et al. (2004) proposed using what they call social adjustment benefits (a type of social psychological motivation) to motivate users to disclose information to enable companies to pursue a strategy of focused marketing. In a more recent study (Xu et al. 2011), monetary compensation and multiple forms of industry regulation were proposed as factors that would both increase perceived benefits and reduce perceived risks of disclosing information to location-aware mobile services. In these examples, the objective is to maximize information disclosure for the benefit of the company.

The other dominant approach takes the side of the consumer in defending them against too-frequent or too-generous privacy disclosure behavior. This literature is focused on the so-called privacy paradox (Acquisti 2004; Acquisti and Grossklags 2003, 2005a,b; Norberg et al. 2007), wherein individuals state salient concerns about privacy and sharing private information, but proceed to behave in ways contrary to their stated beliefs (Norberg et al. 2007). Acquisti and colleagues (Acquisti 2004; Acquisti and Grossklags 2003, 2005a,b; Tsai et al. 2011) have investigated probable causes of this contradictory behavior. Their work serves as an example of research that seeks to benefit the users in protecting them from overgenerous disclosure behavior. They address the issue from a behavioral economics perspective and suggest that the privacy paradox is the result of such limitations as psychological distortions (e.g., hyperbolic discounting of risks), limited or asymmetrical information (because of which users do not know the full implications of disclosure), and bounded rationality (i.e., the inability to accurately process all of the probabilities and amounts of benefits and costs related to privacy disclosure) (Acquisti and Grossklags 2003). It is possibly because of these limitations that users have the tendency to give up private information in return for relatively small conveniences or rewards, even when their stated privacy concerns do not support this behavior. This irrational behavior is generally framed negatively. For example, Tsai et al. (2011) show that when privacy policies are made more obvious and accessible (thus reducing information asymmetries), users tend to act more securely and reduce their disclosure behavior.

55.3.4 Privacy Issues with Deception and Fraud in the Twenty-First Century

When privacy is violated or security breaks down, the results can be far-reaching. Businesses lose billions of dollars each year due to cyber-attacks (Langevin 2011), and our increasingly socially networked world has introduced a new generation of privacy issues (Vaidhyanathan 2011). For example, there are more and more attacks via social networks that directly target individuals (Lewis and Kaufman 2008). This section addresses several topics related to security or privacy threats, as well as some countermeasures that are being developed to reduce those threats.

Though deception and fraud are age-old traditions of the human race, these have become increasingly nuanced since the advent of the Internet and electronic communications, with direct impacts on information security and privacy. Deception, which has been defined (Buller and Burgoon 1996) as "a message knowingly transmitted by a sender to foster a false belief or conclusion by the receiver," can take many forms. These range from impression management activities and half-truths to outright lies and financial fraud. Deception and fraud mediated through electronic channels have major implications for both traditional and digital businesses, as well as for individual consumers.

One common way in which deception and fraud can occur is in relation to products sold by online retailers. This type of deception has been called product-related deception, which is when online merchants deliberately manipulate product-related information with the intent to mislead customers (Xiao and Benbasat 2011). Though product-related deception is not unique to online channels, customers shopping online have fewer cues with which to recognize deception. This makes Internet users more vulnerable to deceptive practices such as product misrepresentation, nondelivery of products, obfuscation of warranty or refund policies, or misuse of personal or financial information (Pavlou and Gefen 2005; Xiao and Benbasat 2011).

Fraudsters seeking to gain financially from their deception have found that the Internet provides many opportunities for financial fraud perpetrated against individual users. One of the more popular schemes involves what is known as *phishing*. In this type of scam, the "phishers" create an e-mail that mimics the look and feel of a legitimate business and asks the user to visit a website to correct some purported technical error. A link is provided that takes them to a fraudulent website constructed to match the legitimate website in every way possible. If an inattentive user attempts to sign in to the website, the phishers are able to obtain the person's username and password, which can then be used to defraud him or her with full online account access.

With phishing, we see a direct relationship between individual-level privacy beliefs and security practices. Phishing is indeed a direct attack on one's online privacy. Unfortunately, research on phishing and related online deception is somewhat sparse. Dhamija et al. (2006) investigated various individual characteristics, including gender, age, computer experience, or education. They found no significant differences in the ability of users to detect deception in fraudulent websites. In a series of studies (Wright et al. 2010; Wright and Marett 2010), students were experimentally phished for private information, and the researchers then accounted for both experiential factors (e.g., computer self-efficacy, web experience) and dispositional factors (e.g., trust, suspicion) in determining whether the deceiver was successful in phishing the sensitive information from the student. The results show that while both sets of factors play a role in how effective a phishing scam will be, experiential factors had a stronger influence on the outcome of the deception. In terms of privacy, the behavioral aspect of information disclosure adds to the complexity when trying to guard against attacks on private or personal information.

55.3.4.1 Countermeasures

To counteract the exponential rise of online fraud and deception (e.g., Gyongyi and Garcia-Molina 2005), systems have been developed with the specific purpose of alerting users to fake or otherwise fraudulent websites. In other words, privacy alerts are now a part of many automated systems.

Currently, these systems vary in sophistication and effectiveness, and users tend to discount their usefulness and avoid adoption (Wu et al. 2006).

Most fraud detection systems use a lookup or classification strategy (Abbasi et al. 2010). A lookup strategy consists of a small client (usually a browser toolbar installed on the user's machine) that connects to a repository of known fraudulent websites (i.e., a blacklist) and then warns the user before a black-listed site is accessed (Wu et al. 2006; Zhang et al. 2007). A classifier system uses characteristics of the website itself to classify the site as either safe or fraudulent, according to rule-based heuristics (Zhang et al. 2007). These characteristics include such cues as domain name, host country, or content similarity (compared to frequently spoofed sites such as eBay or PayPal) (Abbasi et al. 2010). These lookup- or classification-based systems are generally ineffective, with reported accuracy rates of 70% or lower (Abbasi et al. 2010; Zhang et al. 2007).

Recent advances in automated fraud detection systems (e.g., privacy attack systems) have been embodied in a new fraud detection system proposed by Abassi et al. (2010). This system utilizes a statistical learning theory approach to analyze a wider set of cues and domain-specific knowledge. The authors demonstrate that this more advanced detection method outperforms other, less sophisticated systems. Although this and other fraud detection systems have not been heavily adopted by the general public, advancements in this area are encouraging and should help to combat the pervasive fraudulent activity on the Internet. Reducing the incidence of successful phishing and other fraudulent activity should be a primary focus in further protecting users' information privacy.

55.3.4.2 Organizational Issues

Organizations play a pivotal role in the information privacy and security discussion. This is because organizations are primarily charged with protecting individuals' information privacy, either in protecting employees' financial or other personal information, or in protecting the private information they collect about their customers or clients in the course of doing business. A transaction in which an organization acquires any form of private information from a customer must, as a precondition, engender enough trust or goodwill such that the customer is comfortable with the risk of releasing that information to the organization. Culnan and Bies (2003) argue that *any* disclosure of personal information constitutes an assumption of risk on the part of the consumer. Recall that security is a necessary but insufficient condition for protection of privacy (Ackerman 2004), since privacy entails the added assurance that an individual's private information will not be used in a way other than originally intended by the sharer of that information, nor shared with unauthorized third parties (Culnan and Williams 2009).

Given the organizations' responsibility to protect their stakeholders' privacy, information security has become a critical topic for organizations. Researchers have noted vital financial and legal implications for failing to protect information privacy (Goel and Shawky 2009; Gordon and Loeb 2002). It has also been proposed that a majority of organizational security issues are related to human error or noncompliance with security policies (Stanton et al. 2005). Accordingly, organizations have reported employees' security-related behavior as a top concern for years (Boltz 2011). The issues that organizations cope with, and the countermeasures that they implement, thus result from tendencies of their employees' individual behaviors.

55.3.5 Security Policies/Compliance

As concerns regarding privacy and security have increased, organizations have implemented privacy and security policies to help inform employees of standards and to enforce security precautions where necessary to ensure the privacy of the organization's data and employees. Hone and Eloff (2002) identify the information privacy and security policy, the most singularly important security control that an organization can implement. This view is also shared by others (Knapp et al. 2009; Whitman 2008).

An information privacy and security policy is established to provide management direction and support for information privacy and security as derived from business requirements and relevant laws and

regulations (Knapp et al. 2009). Policies generally consist of a general objective or purpose, a stated scope indicating to whom the policy applies, assigned responsibilities where various organizational roles are given ownership over various portions of the policy, and guidelines for compliance, which provide for the policy's enforcement (Olzak 2006). These are general guidelines that vary according to an organization's needs.

That an entire body of literature (noted earlier) has developed around employee noncompliance with security policies is an indication that many policies or portions of policies are not regularly followed by employees. This represents a serious problem for organizations, since noncompliance by even a few employees can largely negate the benefits of even the most stringent of policies. Organizations must strike a balance between instituting policies that are overly restrictive, which can lower productivity or instill contempt among annoyed employees, and policies that are not restrictive enough, which largely defeats the purpose of a security policy. This balance is elusive, and privacy and security policy compliance continues to fuel discussion and investigation in the literature.

55.3.6 Legal Requirements (SOX, GAAP, Others)

Following the several cases of corporate accounting fraud shortly after the turn of the century, the most notable of which were the Enron and WorldCom scandals, the U.S. government enacted legislation designed to close accounting loopholes and generally tighten controls on accounting practices. This legislation, termed the Sarbanes-Oxley (SOX) Act, has had far-reaching effects, many of which have directly impacted the IS function in many organizations (Volonino et al. 2004). Among the requirements detailed in the SOX bill, companies must ensure transparency, accuracy, timeliness, and reliability of their IT-enabled financial reporting and operations systems. These requirements necessitate security policies and managerial oversight to ensure employee compliance with those policies. Indeed, Volonino et al. (2004) state that "to be in compliance with regulatory boards, companies need to develop and deploy effective information security response and investigation policies. Those policies will require collaboration between corporate IT security teams and IT auditors" (p. 226).

In summary, organizations have the responsibility to ensure the security and privacy of their employees and customers. To accomplish this, most organizations employ official policies requiring certain levels of private and secure behavior. Though noncompliance with these policies is the object of considerable research in the literature, organizations continue to strive to provide for their stakeholders' privacy and security.

55.4 Future Research Agendas

This chapter has identified the major theoretical perspectives and some current privacy- and security-related problems and solutions. Clearly, there are many associated research opportunities that IS scholars can address. The following will outline three areas within privacy and security that we believe have the potential to impact end users, organizations, and society in general. We will first explore interesting questions in the design for privacy and security.

55.4.1 Designing for Privacy and Security

Consistent with the theme of individual behaviors that persists in this chapter, we will look toward design as an avenue that affects privacy and security for individuals. Specifically, we will address the balance between allowing end users to act and automating privacy and security tasks. Within application design, security tools have either focused on being invisible (e.g., filters, automated messages, and so on) or attaching attention (e.g., call outs, security alerts, and so on) (Hong 2012). Although there are mixed results, what is clear is that no single method can achieve the results needed for 100% secure practices that ensure one's privacy. Further, since privacy is individually constructed, one system run by homogenous business rules would likely meet with user resistance or nonadoption. For this reason, the first step

toward understanding the design elements for secure IT systems is to develop a framework that includes the invisible (e.g., automatic systems) and the visible (e.g., warnings and human decision points). The need for this framework is echoed in Sheng et al.'s (2010) phishing research, which identifies clear gaps between the heuristics (e.g., the decision process for end users) and machine-learning algorithms (e.g., anti-phishing toolbars). Other general privacy and security research has followed this pattern. In order to solve complex phenomena such as privacy and security issues, it will take a multidisciplinary effort from psychologists, computer scientists, and IS scholars. With multidisciplinary efforts, we will be able to address significant privacy and security questions that are as follows:

1. What privacy decisions are best made using machine learning and which are best left to humans?
2. How should machine-learning algorithms interact with end users?
3. Is there a theoretical perspective that could integrate the need for visibility and invisibility of certain processes?

By attempting to address these questions, the privacy researchers should coalesce around common themes within this important domain.

55.4.2 Understanding Training

Training has been posited as the main defense against directed attacks (Hong 2012). In fact, there has been a variety of training experiments by the anti-phishing group at Carnegie Mellon University (CMU) (Kumaraguru et al. 2009; Sheng et al. 2010). Hong states that "it doesn't matter how many firewalls, encryption software, certificates, or two-factor authentication mechanisms an organization has if the person behind the keyboard falls for a phish" (Hong 2012, p. 76). Training against phishing has taken two lines. First, the CMU group and others have designed microgames that teach employees how to spot phishing messages (Sheng et al. 2007). The second is embedded training in which participants are sent phishing messages in a classroom setting and are asked to evaluate these. Kumaraguru et al. (2009) found this approach to be effective even a month after training. These phishing training mechanisms may offer other areas a clear path for implementation. Some questions around privacy and security include the following:

1. Are some training techniques better than others (e.g., mindfulness training, cognitive trainings)?
2. What are the best delivery mechanisms for training (e.g., online, classroom, games)?
3. How do you combine privacy and security training?
4. What are the biggest gaps in training for employees? For consumers?

Obviously, there are many other opportunities for training research that can be considered. It is important first to address the big IS questions using a multidisciplinary point of view and expertise as stated earlier.

55.4.3 Looking at Information Systems' Policy Differently

A lot of attention is currently paid to employee compliance with privacy and security policies (Hone and Eloff 2002; Knapp et al. 2009; Whitman 2008). In fact, most of the theoretical work is geared toward understanding why an organization's personnel comply with the policy or not (e.g., PMT, deterrence theory, and so on). What is not clear is how the policy itself may enact certain behaviors from employees and consumers. The following research questions are appropriate starting points to address how policy affects behavior:

1. Is there a better way to classify the interplay between IS security policies and privacy beliefs?
2. What is the impact of less-restrictive IS polices on the work force?
3. How do privacy and security policies impact productivity?
4. Do privacy policies influence e-commerce interactions?

In sum, there are multiple interesting angles from which to study privacy and security policy issues that are yet to be explored. These and others represent excellent opportunities for future knowledge creation.

55.5 Conclusion

This chapter outlines the current issues with information privacy and security. In doing so, we have provided a framework that summarizes the interplay between users' concerns regarding information privacy and the provision of that privacy through the three basic components of security assurance: (1) authentication, (2) confidentiality, and (3) integrity. Further, we provide the current state of research at the individual and organizational levels of analysis. Finally, we identify three gaps in privacy and security research that IS scholars should address (i.e., design issues, training, and policies).

Digital Forensics

Vassil Roussev
University of New Orleans

56.1 Introduction

Forensic science (or *forensics*) is dedicated to the systematic application of scientific methods to gather and analyze evidence in order to establish facts and conclusions that can be presented in a legal proceeding. Digital forensics (a.k.a. computer or cyber forensics) is a subfield within forensics, which deals specifically with digital artifacts, such as files, and computer systems and networks used to create, transform, transmit, and store them. This is a very broad definition, and there are several closely related fields and sub-fields that share methods and tools with forensics. Indeed, the forensic methods used were originally developed for a different purpose and continue to be shared. Thus, it is primarily the *purpose*, and not their functionality, that classify particular tools and techniques as forensic.

Malware analysis [Mali08] (or *malware forensics*) specializes in understanding the workings and origins of malicious software, such as viruses, worms, trojans, backdoors, rootkits, and bots. Such analysis is often necessary after a security breach to understand the exploited vulnerability vector and the scope of the breach. The analysis depends on well-prepared and executed *incident response* phase, which identifies and collects the source data for the analysis, while restoring the affected IT systems to a known good state.

Reverse engineering, the process of inferring the structure, or run time behavior of a digital artifact, is almost always a critical step in any kind of forensic analysis. Apart from the obvious example

of malware, most closed-source software produces artifacts that are rarely publicly documented by the vendor (unless they want to establish them as a standard). For example, the on-disk structure of Microsoft's NTFS file system has never been officially published; the format of the files used by Microsoft Office was not officially released until 2008.*

Data recovery, the process of salvaging useable digital artifacts from partial or corrupted media, file systems, or individual files is another technique frequently employed in forensics during the initial, data acquisition, stage. More broadly, the definition of data recovery often includes the retrieval of encrypted, or otherwise hidden, data.

The intelligence community uses *document and media exploitation* (or *DOMEX*) [Garf07b] to extract actionable intelligence from relevant data sources. In practice, the DOMEX relies heavily on available forensic techniques, and higher-level analysis, to make sense out of large amounts of raw data.

The goal of this chapter is to present an overview of the state of the art in digital forensics from a technical perspective, with an emphasis on research problems. This allows us to treat the topic in a more holistic manner by presenting issues, tools, and methodologies that are common to a broader field in computer security and IT management. The legal aspects of computer forensics, which is clearly of concern to practitioners in law enforcement, can largely be modeled as placing various restrictions on the ways in which the data can be gathered and the way conclusion can be presented in a courtroom. These do present some additional research and development problems; however, these are relatively minor.

56.2 Definitions

The overall objective of digital forensic analysis is to reconstruct a chain of events that have resulted in the currently observable state of a computer system or digital artifact. The purpose of the analysis is to help answer six basic questions that arise in most inquiries: *what* happened? *where* did it happen? *when* did it happen? *how* did it happen? *who* did it? *why* did they do it? Any notion of completeness of the analysis, which can be of legal significance, is tied to the target and purposes of the original investigation and is very difficult to define in technical terms.

Another approach to understanding cyber forensics is to view it from a procedural standpoint—what does a typical investigation entail? This is an important question as one of the cornerstones of scientific processes is that the observed results must be independently reproducible. There are four generally accepted [Kent06] steps in the forensics process: *collection*, *extraction*, *analysis*, and *reporting. Examiner preparation*, in which the investigator is trained to perform the specific type of investigation, is sometimes referenced as an added, preliminary step.

During the collection phase, the investigation must identify potential sources of evidence (computers, mobile phones, flash/optical media, etc.) and choose, acquire, and preserve the appropriate ones based on the objective of the inquiry and legal restrictions. We will largely ignore this phase as it is an issue of procedure and training, not science. Similarly, the reporting phase during which investigators prepares a report and testifies will also be outside the scope of this discussion.

The main focus will be on the extraction and analysis phases, which constitute the most technically challenging parts. The investigator goes through the process of forming an initial hypothesis, searching for evidence that supports/disproves it, refining/redefining the hypothesis and going back to the data for proof. This process goes through multiple iterations, until the analyst has reconstructed the sequence of relevant events with the necessary level of certainty.

Throughout, examiners must carefully preserve the evidence and document the tools used and actions taken to demonstrate the reproducibility of their analysis.

For the remainder of the chapter, we look at the investigative process from four different perspectives in an effort to provide a comprehensive view of the field. First, we look at general models and best

* http://msdn.microsoft.com//en-us//library//cc313118.aspx

practices of digital forensic inquiries that have slowly emerged over the years and can serve as a useful guide as to how a particular type of investigation should be performed.

Next, we consider forensic methods as they relate to main system components of a general purpose computing infrastructure—secondary storage, main memory, and networks—as well as the additional challenges posed by various integrated devices. Next, we consider the major types of artifacts that are typically of interest to an investigation—text, multimedia data (audio/video), executable code, and system data. Most of these have standardized (file) container formats, which allows their analysis to be decoupled from that of the source. Analytic methods in this domain can readily borrow from other fields like information retrieval and signal processing.

Finally, we consider the specific requirements that digital forensic tool developers face. Some of these, such as the efficient use of commodity parallel computing, are shared with other application domains, while others, like the potential need to comply with legal restrictions, are very specific to forensics.

56.3 Inquiry Models and Tool Uses

Over the past decade, both researchers and practitioners have been working to summarize, classify, and formalize the understanding of digital forensic tools and processes. In broad terms, models coming from practitioners, such as investigators in forensic labs, tend to describe the process as a collection of detailed procedures for routine operations (e.g., disk cloning) and high-level "best practices". Work coming from researchers tends to focus on technical aspects of how to deal with specific problems—data recovery, search and query, etc. These models are difficult to compare with each other as they effectively speak to different parts of the problem and in different languages.

To present a unified picture of the digital forensic process, we adapt the sense-making process originally developed by Pirolli and Card [Piro05] to describe intelligence analysis. This is a cognitive model derived from an in-depth *cognitive task analysis* (CTA), which provides an overall view of an intelligence analyst's work. Although some of the tools used may vary, forensic analysis is very similar in nature to intelligence analysis—in both cases analysts have to go through a mounting of raw data to identify (relatively few) relevant facts and put them together in a coherent story.

The benefit of using the Pirolli and Card model is at least threefold: (a) it provides a fairly accurate description of the investigative process in its own right and allows us to map the various tools to the different phases of the investigation; (b) it provides a suitable framework for explaining the relationships of the various models developed within the area of digital forensics; and (c) it can seamlessly incorporate information from other lines of the investigation.

56.3.1 Pirolli and Card Cognitive Model

The overall process is shown in Figure 56.1. The rectangular boxes represent different stages in the information processing pipeline, starting with raw data and ending with presentable results. Arrows indicate transformational processes that move information from one box to another. The x axis approximates the overall level of effort to move information from raw to the specific processing stage. The y axis shows the amount of structure (with respect to the investigative process) in the processed information for every stage. Thus, the overall trend is to move the relevant information from the lower left to the upper right corner of the diagram. In reality, the processing can both meander through multiple iterations of local loops, and to jump over phases (for routine cases handled by an experienced investigator).

External data sources include all sources of potential evidence for the specific investigation, such as disk images, memory snapshots, network captures, as well as reference databases, such as hashes of known files. The *shoebox* is a subset of all the data that has been identified as potentially relevant, such as all the email communication between two persons of interest. At any given time, the contents of the shoebox can be viewed as the analyst's approximation of the information content potentially relevant to the case. The *evidence file* contains only the parts that directly speak to the case, such as specific email

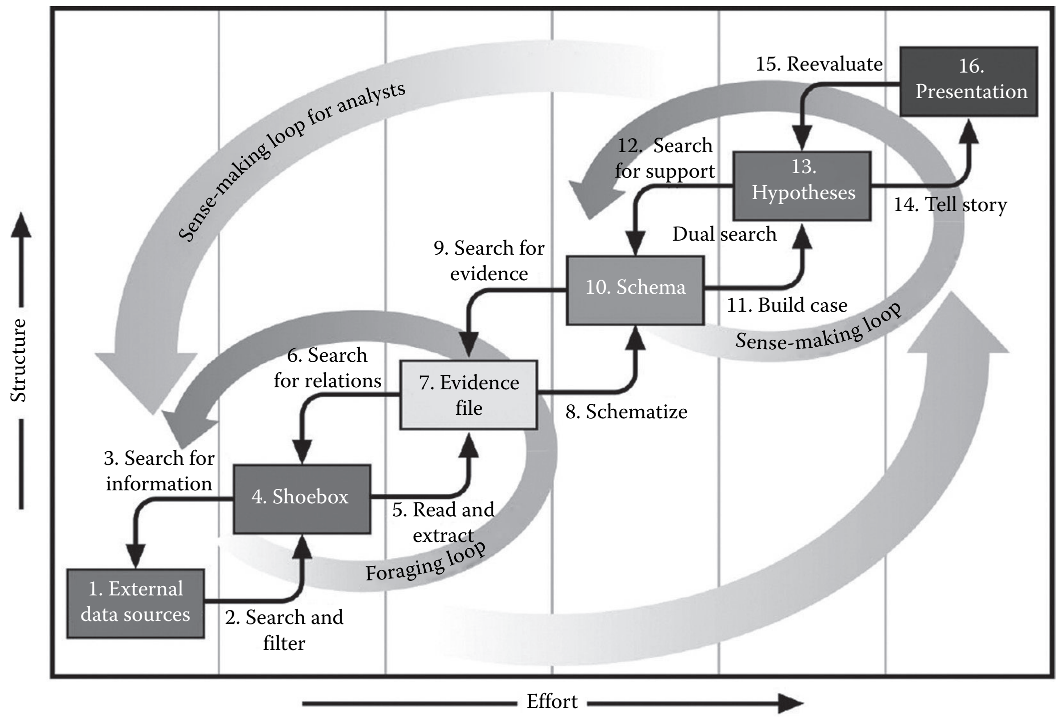

FIGURE 56.1 Notional model of sense-making loop for analysts derived from CTA. (Thomas, J. and Cook, K., (eds.), *Illuminating the Path: The Research and Development Agenda for Visual Analytics*, IEEE CS Press, Piscataway, NJ, 2005.)

exchanges on the topic of interest. The *schema* contains a more organized version of the evidence, such as a timeline of events, or a graph of relationships, which allows higher-level reasoning over the evidence. A *hypothesis* is a tentative conclusion that explains the observed evidence in the schema and, by extension, could form the final conclusion. Once the analyst is satisfied that the hypothesis is supported by the evidence, the hypothesis turns into a *presentation*, which is the final product of the process. The presentation usually takes on the form of an investigator's report that both speaks to the high-level conclusions relevant to the legal case, and also documents those low-level technical steps based on which the conclusion has been formed.

The overall analytical process is split into two main activities loops: (1) a *foraging loop* that involves actions taken to find potential sources of information, query them, and filter them for relevance; (2) a *sense-making* loop in which the analyst develops—in an iterative fashion—a conceptual model that is supported by the evidence. The information transformation processes in the two loops can be classified into bottom-up (organizing data to build a theory) or top-down (finding data based on a theory) ones. In practice, analysts apply these in an opportunistic fashion with many iterations.

56.3.1.1 Bottom-Up Processes

Search and filter: External data sources, hard disks, network traffic, etc. are searched for relevant data based on keywords, time and other constraints, in an effort to eliminate the vast majority of the data that are irrelevant.

Read and extract: Collections in the shoebox are analyzed to extract individual facts and relationships that can support or disprove a theory. The resulting pieces of artifacts (e.g., individual email messages) are usually annotated with their relevance to the case.

Schematize: At this step, individual facts and simple implications are organized into a schema that can help organize and help identify the significance and relationship among a growing number of facts and events. Timeline analysis is one of the basic tools of the trade; however, any method of organizing and visualizing the facts—graphs, charts, and diagrams—can greatly speed up the analysis. This is not an easy process to formalize, and most forensic tools do not directly support it. Therefore, the resulting schemas may exist on a piece of paper, or on a whiteboard, or only the mind of the investigator. Since the overall case could be quite complicated, individual schemas may cover specific aspects of it, such as the sequence of events discovered.

Build case: Out of the analysis of the schemas, the analyst eventually comes up with testable theories that can explain the evidence. A theory is a tentative conclusion and often requires more supporting evidence, as well as testing against alternative explanations.

Tell story: The typical result of a forensic investigation is a final report and, perhaps, an oral presentation in court. The actual presentation may only contain the part of the story that is strongly supported by the digital evidence; weaker points may be established by drawing on evidence from other sources.

56.3.1.2 Top-Down Processes

Re-evaluate: Feedback from clients may necessitate re-evaluations, such as the collection of stronger evidence, or the pursuit of alternative theories.

Search for support: A hypothesis may need more facts to be of interest and, ideally, would be tested against alternative explanations.

Search for evidence: Analysis of theories may require the re-evaluation of evidence to ascertain its significance/provenance, or may trigger the search for better evidence.

Search for relations: Pieces of evidence in the file can suggest new searches for facts and relations on the data.

Search for information: The feedback loop from any of the higher levels can ultimately cascade into a search for additional information—that may include new sources, or the re-examination of information that was filtered out during previous passes.

56.3.1.3 Foraging Loop

It has been observed [Patt01] that analysts tend to start with a high-recall/low-selectivity query, which encompassed a fairly large set of documents—many more than the analyst can afford to read. The original set is then successively modified and narrowed down before the documents are read and analyzed.

The foraging loop is a balancing act between three kinds of processing that an analyst can perform—explore, enrich, and exploit. Exploration effectively expands the shoebox by including larger amounts of data; enrichment shrinks it by providing more specific queries that include fewer objects for consideration; exploitation is the careful reading and analysis of an artifact to extract facts and inferences. Each of these options has varying cost and potential rewards and, according to information foraging theory [Piro09], analysts seek to optimize their cost/benefit trade-off.

56.3.1.4 Sense-Making Loop

Sense-making is a cognitive term and, according to Klein's [Klei06] widely quoted definition, is the ability to make sense of an ambiguous situation. It is the process of creating situational awareness and understanding to support decision making under uncertainty—an effort to understand connections among people, places and events in order to anticipate their trajectories and act effectively.

There are three main processes that are involved in the sense-making loop: *problem structuring*—creation and exploration of hypotheses, *evidentiary reasoning*—the employment of evidence to support/disprove hypothesis, and *decision making*—selecting a course of action from a set of available alternatives.

56.3.2 Model Relationships

Using the previously mentioned cognitive model, we can map different conceptual approaches to modeling the forensic process. *Mathematical* models are suitable for relatively small components of investigative process. They can formalize individual steps in the analysis, such as inferring specific events based on the observed state of the system, or can be used to formalize hypotheses and test them using statistical means. Thus, mathematical models can support specific steps—either bottom-up or top-down—in the analytical process, but it is infeasible to model the entire investigation.

Procedural models come from practitioners and tend to be very linear, essentially, prescribing an overall march from the lower left to the upper right corner (Figure 56.1) while applying the available tools. These are not true scientific models but compilations of best practices based on experience.

Legal models of forensics come from the consumers of the final product of the analysis—legal experts—who have little, if any, technical expertise. They can be viewed as imposing boundary conditions on the process: they restrict what part of the available data may be investigated (e.g., no privileged communication), and formulate the required end result requirements (e.g., prove that the suspect was *knowingly* in possession of contraband material, and had the intent to distribute it). Despite some early efforts, such by Xu et al. [Xu09], these requirements and restrictions are too arbitrary and case-specific to be efficiently translated into technical requirements.

56.3.3 Mathematical Models

An alternative to the Pirolli and Card (P&C) cognitive model is to present the forensic process as reconstructing the history of a computation using mathematical formalisms. Carrier proposed one such model [Carr06a] which makes the assumption that the computer system being investigated can be reduced to a finite state machine (FSM) with set of states Q. The transition function is the mapping between states in Q for each event in the event set, and the machine state changes only as a result of an event.

The point of Carrier's model is not to reduce a system to an enormous FSM but to find basic building blocks from which to build higher-level constructs, while establishing properties using formal methods. In this model, one could formulate a formal hypothesis and test it against the captured state and the known capabilities (transitions) of the system. The model is lower-level than procedural frameworks and analytic taxonomies; therefore, it offers the promise of providing formal proofs to show the completeness of the analytic techniques employed.

Statistical approaches have the potential to be more practical by enabling formal hypothesis testing and quantifying the level of confidence in the conclusions. For example, Kwan et al. [Kwan08] and [Over10] et al. show how Bayesian networks can be used to evaluate the strength of the evidence for some simple cases and study the sensitivity of the model to inputs. The primary challenge, however, is providing reliable estimates of the various probabilities upon which the model depends.

56.4 System Analysis

In this section we outline the various approaches to acquiring and analyzing the content of a computer system; specifically, we consider the examination of persistent storage, main memory, and network communications.

56.4.1 Storage Forensics

Persistent storage in the form of hard drives, optical disks, flash device, etc. is the primary source of evidence for most digital forensic investigations, in terms of both volume and importance. For example, during FY 2010, the average investigation at FBI's Regional Computer Forensics Labs consisted of 470 GB of data [FBI10], and the vast majority of the data comes from hard disks.

Storage analysis, detailed by Carrier [Carr05], can be performed at several levels of abstraction:

- *Physical media*: At the lowest level, every storage device encodes a sequence of bits and it is, in principle, possible to use a custom mechanism to extract the data bit-by-bit. In practice, this is rarely done as it is an expensive and time-consuming process. The only notable exception is second-generation mobile phones for which it is feasible to physically remove (desolder) the memory chips and perform acquisition of content; Willasen [Will05] provides a detailed account of the process. Thus, the lowest level at which most practical examinations are performed is the host bus adapter (HBA) interface. Adapters implement a standard protocol (SATA, SCSI, etc.) through which they can be made to perform low-level operations. For damaged hard drives, it is often possible to perform at least partial forensic repair and data recovery [Moul07]. In all cases, the goal of the process is to obtain a copy of the data in the storage device for further analysis.
- *Block device*: The typical HBA presents a block device abstraction—the medium is presented as a sequence of fixed-size blocks, commonly of 512 or 4096 bytes, and the contents of each block can be read or written using block read/write commands. The media can be divided into partitions, or multiple media may be presented as a single logical entity (e.g., RAIDs). The typical data acquisition process works at the block device level to obtain a working copy of the forensic target—a process known as *imaging*—on which all further processing is performed.
- *File system*: The block device has no notion of files, directories, or even which blocks are considered "used" and which ones are "free"; it is the file system's task to organize the block storage into a file-based storage in which applications can create files and directories with all of their relevant attributes—name, size, owner, timestamps, access permissions, and others. For that purpose, the file system maintains metadata in addition to the contents of user files.
- *Application*: User applications use the file system to store various artifacts that are of value to the end-user—documents, images, messages, etc. The operating system itself also uses the file system to store its own image—executable binaries, libraries, configuration and log files, registry entries—and to install applications.

Overall, analysis at the application level yields the most immediately useful results as it is most directly related to actions and communications initiated by humans. Indeed, most integrated forensics tools present a file system browser as their basic user interface abstraction. Yet, they also provide additional information that is not readily accessible through the normal operating system user interface. Such information is derived from additional knowledge of how a particular operating system works and what the side effects of its storage management techniques are.

One important source of additional data is the recovery of artifacts that have been deleted, or are otherwise not completely recoverable due to hardware errors. An extreme example of that is a used hard disk drive that has been freshly formatted—to the regular file browser interface, it would appear that the device is completely empty. In reality, only a small fraction of the drive has been overwritten—just enough to create blank file system metadata structures. The rest of the drive is marked as available but the previous content is still there, and that includes the complete content of almost all the files. In fact, the content would survive multiple formatting operations and, depending on usage patterns, data could be found years after its intended removal.

56.4.1.1 Target Acquisition

In line with best practices [Kent06], file system analysis is not carried out on a live system. Instead, the target machine is powered down, an exact bit-wise copy of the target disk is created, the original is stored in an evidence locker, and all forensic work is performed on the copy.

There are exceptions to this workflow in cases where it is not practical to shut down the target system and a live disk image from a running target is obtained; evidently, the consistency of data in use cannot be guaranteed. In virtual environments, a standard snapshot of the virtual disk can be trivially obtained.

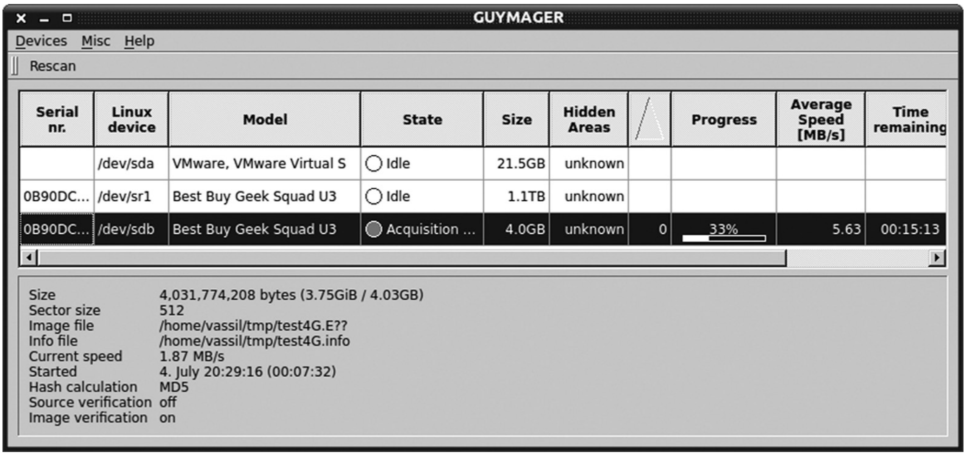

FIGURE 56.2 Screenshot of *guymage* during target acquisition.

The copy process of a physical disk can be accomplished in software, hardware,[*] or combination of both. The original workhorse of forensic imaging has been the *dd* Unix/Linux general purpose command-line utility, which can produce a binary copy of any file, including special files representing entire storage devices. For example, the simple command `dd if=/dev/hda1 of=target.dd`, would produce a binary copy of the first partition of the first disk drive and will place it in the *target.dd* file. A hardware *write blocker*[†] is often installed on the target device to eliminate the possibility of operator error that leads to the accidental modification of the target. Further, cryptographic hashes are computed for the entire image and (optionally) for every block. The latter can be used to demonstrate the integrity of the evidence if the original device suffers a partial failure, which makes it impossible to read its entire contents. To simplify the acquisition process, more specialized versions of *dd*, such as *dcfldd*,[‡] provide additional functionality, such as hashing and integrity verification on-the-fly, multiple output streams, and logging. A more advanced tool geared specifically toward forensics is the *guymager*[§] target acquisition tool (Figure 56.2), which provides additional output options beside the raw image produced by *dd*.

Ddrescue[¶] is another variation on *dd*, which automatically tries to recover from read errors over multiple runs in an effort to extract as much data as possible from a failing hard drive. Virtually all commercial tools, as well as a number of other open source projects, provide the basic disk imaging capability, and it is beyond the scope of this discussion to provide an exhaustive enumeration. The National Institute of Justice sponsors the Computer Forensic Tool Testing (CFTT) project,[**] which independently tests various basic tools, such as write blockers and image acquisition tools and regularly publishes reports on its findings.[††]

56.4.1.2 File Carving and Reconstruction

Generally, data stores with dynamic allocation, such as file systems, main memory, and databases, contain left over data that are not immediately accessible via the regular programming interface but are recoverable by direct examination of the raw data. For example, a file deleted by the user is simply marked as deleted and its storage allocation is reclaimed only when the need arises, which could happen anywhere from

---

[††] http://www.cftt.nist.gov/disk_imaging.htm

milliseconds to never. Main memory content can also persist for a long time as many computer systems are not reset for long periods of time, and even reboots may not clear memory [Hald08].

This behavior may be surprising to users, but it is primarily the result of performance considerations in the operation of software that manages the data. Sanitizing the de-allocated storage can be very expensive not only when applied to a hard disk but also to main memory management. This is a known security problem and solutions have been proposed [Chow05], but they are not routinely employed. Another reason to find data not actively in use in main memory is caching—perhaps the oldest performance optimization trick. Modern software systems use multiple levels of caching with the goal of minimizing secondary storage access, so data tends to persist where it was not intended to—main memory.

Forensic computing, unlike most other types of computations, is most keenly interested in *all* extractable artifacts, including—and sometimes *especially*—de-allocated ones. Unless a user has taken special measures to securely wipe a drive, it is reasonable to expect that, at any given time, the media contains recoverable applications artifacts—primarily files—that are ostensibly deleted.

File carving is the process of recovering application files directly from block storage without the benefit of file system metadata. The essential observation that makes this possible is twofold: (a) most file formats have specific beginning and end tags (a.k.a. *header* and *footer*); and (b) file systems heavily favor sequential file layout for better performance. We briefly survey the research and tool development in file carving; a more detailed look at the evolution of file carving techniques can be found in [Pal09].

In the simplest case, a file carving tool sequentially scans through a device image and looks for known headers at block boundaries. If a header is found, then the tool looks for a corresponding footer and, upon success, copies (carves out) all the data in between the two tags. For example, a JPEG image always starts with the header (in hexadecimal) `FF D8 FF` and ends with `FF D9`. In practice, things are a bit more complicated since file formats were never designed for this type of processing and can have weak distinguishing features or may embed other file types (e.g., JPEGs can have an embedded thumbnail, also in JPEG). Further, actual data layout often has gaps, mixed-in blocks from other files, or outright data losses.

One of the first tools to implement the previously mentioned idea and gain popularity among forensic professionals was *foremost*.* It is a command-line utility which uses a configuration file for header/footer definitions and has some built-in parsing functions to handle Microsoft Office (OLE) files. *Scalpel*† [Rich05] is a file carver originally conceived as an improved implementation of *foremost* and utilizes a two-pass strategy to optimize work schedules and reduce the amount of redundant data being carved. Subsequent optimizations [Marz07] allowed the tool to utilize parallel CPU and GPU processing.

The development of new file carving techniques has been pushed forward by the 2006 [Carr06b] and 2007 [Carr07], DFRWS Challenges, which provided interesting scenarios for tool developers to consider. Garfinkel [Garf07a] performed a statistical study of actual used hard drives purchased on the secondary market and found that most fragmented files are split in two pieces and are, therefore, still recoverable with reasonable effort. He also presented a proof-of-concept approach based on using application-level verification.

Sencar and Memon [Senc09] developed a robust algorithm and a specialized tool that can carve out JPEG fragments and successfully reassembles them using image analysis techniques. The tool has been subsequently commercialized and can be useful to regular users to recover images from flash memory used in digital cameras.

Looking ahead, file carving is likely to be a useful tool for the foreseeable future as hard disk sizes continue to grow and it becomes ever more performance-critical for file systems to lay out files sequentially. At the same time, King and Vidas [King11] have established experimentally that file carving would only work in a narrow set of circumstances on modern solid state drives (SSD). The reason lies in the fact that

* http://foremost.sourceforge.net
† http://www.digitalforensicssolutions.com/Scalpel/

SSD blocks need to be written twice in order to be reused—the first write resets the state of the block, thereby enabling its reuse. To improve performance, the *trim* command was added to the SATA protocol specification to allow the operating system to garbage collect blocks not in use and make them ready for reuse. Virtualized cloud storage represents another limitation to file carving as de-allocated data are automatically sanitized to prevent data leaks across tenants.

56.4.1.3 File System Analysis

Once a working copy of the investigative target has been obtained, the actual analysis can commence in earnest. The first goal is to identify and gain access to all the artifacts stored on the media—files, directories, email messages and other personal communications, system registry entries, etc. The complete recovery of all useable artifacts requires deep understanding of the physical layout of the on-disk structure of the specific version of the specific operating system. This is a particularly thorny issue with proprietary file systems, such as the MS Windows family, as their structures are not publicly documented and need to be reverse-engineered. Fortunately, the open-source community at large has tackled many of these problems for interoperability reasons, and has developed some robust implementations.

It is useful to place the forensically significant file system data into two categories—system artifacts and application artifacts—which we discuss for the rest of this section.

System artifacts: The operating system continuously generates traces of its users' activities. Some pieces of this information are quite obvious—automatic updates to timestamp file attributes—others are more obscure, such as system log entries. More subtle information can be obtained by observing the physical layout of the files on the block devices. In Unix/Linux, the structure containing the metadata for a file is called an *i*-node and each file is associated with a particular *i*-node. Normally, files created in a quick succession (during installation) would have the same creation timestamp and *i*-node numbers that are close to each other. However, if we find a file which blends in based on timestamp but has an uncorrelated *i*-node number (suggesting creation at a later time), this would be an outlier event worthy of further investigation.

We use *The Sleuthkit**(*TSK*), the most popular open source tool for file system forensics, to illustrate the system artifacts that are commonly used in a forensic investigation. TSK is C/C++ library, as well as a collection of command-line tools. TSK's code is based on The Coroner's Toolkit (TCT), which was originally created by Dan Farmer and Wietse Venema and featured in their classic book on forensics [Farm05]. The scope of TCT was expanded from the original target of Unix files systems to include MS Windows and MacOS formats.

TSK provides over 20 individual tools that can provide file system information at different levels of abstraction. Here, we provide a sampling of the more important ones.

Metadata layer tools process the on-disk metadata structures created by the file system to store standards attributes of a file—name, size, timestamps, etc. Under normal operating system operation, these structures are only available to the kernel. This toolset, however, allows the direct access to the following structures:

- *ifind* finds the metadata structure that has a given file name pointing to it or the metadata structure that points to a given data unit;
- *icat* extracts the data units of a file, which is specified by its metadata address;
- *ils* lists the metadata structures and their contents;
- *istat* displays the statistics and details about a given metadata structure.

Many modern file systems, such as ext3 and NTFS, employ a journaling (log) function, which keeps track of attempted file operation. Should the system crash, the journal allows for the replay of these operations and thus minimizes the loss of data to the user. TSK contains two tools—*jls* and *jcat*—that list the entries in the file system journal and can display the contents of a specific journal block, respectively. This enables an investigator to recover additional information that is not otherwise accessible.

* http://sleuthkit.org

The purpose of the *block device* tools is not just to provide access to individual data blocks but also to assign meaning to the content of the block. Specifically, we could target individual blocks that are allocated, unallocated, or we could identify and gain access to the slack space at the end of a block:

- *blkcat* extracts the contents of a given data unit (block);
- *blkls* lists the details about data units and can extract the unallocated space of the file system;
- *blkstat* displays the statistics about a given data unit in an easy-to-read format;
- *blkcalc* calculates where data in the unallocated space image (from *blkls*) exist in the original image. This is used when evidence is found in unallocated space.

Volume system tools take an image as input and analyze its partition structures. These can be used to find hidden data between partitions and to identify the file system offset for TSK:

- *mmls* displays the layout of a disk, including the unallocated spaces;
- *mmstat* displays details about a volume system (the type);
- *mmcat* extracts the contents of a specific volume.

As the previous descriptions suggest, in every group of tools, we can find a "stat" tool, which provides basic information (statistics) for the relevant data structures; an "ls" tool, which enumerates data structures of a particular kind; and "cat" tools, which interpret and extract the data from the structures.

The *Autopsy Forensic Browser* provides a simple Java-based graphical interface to TSK, as well as a framework that allows third-party components to be added to the processing pipeline. The goal of the project, still in its early stages, is to put together an open integrated environment that improves the usability of open source tools and enables further extension of functionality.

The *registry* is a central hierarchical database of key/value pairs used in all versions of Microsoft Windows to store information that is necessary to configure the system for one or more users, applications, and hardware devices. As such, the registry is a treasure trove for an investigator as it records a large number of values that can indicate user and application activity from recently used files, to traces of uninstalled applications, to records of external storage devices that have been connected to the system.

Tools like RegRipper* and RegistryDecoder† offer the option of extracting any available information from the registry. Since a registry contains tens/hundreds of thousands of entries, the investigator must have a fairly specific idea of what to look for. Figure 56.3 shows RegistryDecoder in action, where it has recovered the list of USB devices seen by the system and allows the investigator to tie the computer system to specific devices, including in this case a mobile phone.

Modern operating systems automatically create copies of user and system data in order to both improve reliability, by being able to reset to a known good state, and to support user data backup needs. In MS Windows, the service is called *Volume Shadow Copy Service*‡ and captures stable, consistent images for backup on running systems under a variety of circumstances with regular users largely unaware of its operation. As a result, a forensic analyst can retrieve the prior state of the system, including artifacts that the user might have securely deleted [Harg08].

The file systems used by Unix derivatives—HFS+ on MacOS, ext3/ext4 on Linux, and ZFS on Solaris—use journaling as a basic reliability mechanism. By understanding the structure of the journal entries, it is possible to recover the recent history of file operations [Burg08, Fair12, Beeb09].

Application artifacts: An analyst can gain access to all the files created explicitly and implicitly by the user. Most users are well aware of the files they create explicitly (documents, images, emails), and a guilty user may try to cover their tracks by removing incriminating ones. Yet, computer systems tend to create multiple copies of the same information and can be very difficult to dispose them all. Modern applications contain numerous features to help the user by remembering preferences and histories, as well as

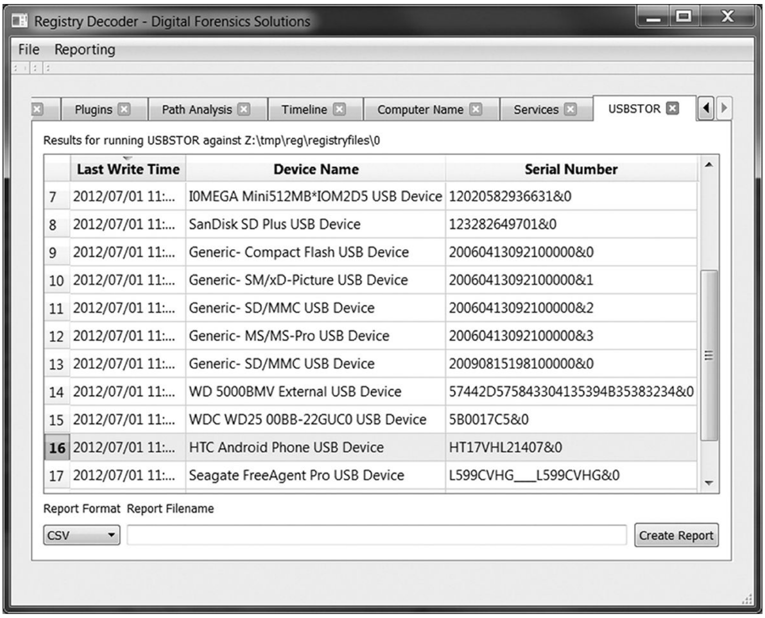

FIGURE 56.3 *RegistryDecoder* shows a list of USB devices that had been connected to the system.

automation features such as recovery of previous document versions and automatic filling of author, date, title, and other properties. These could all be exposed and, together with the documented behavior of the application, could bear witness to what users did. It is fair to say that many applications are also sloppy during uninstall procedures and can leave (sometimes deliberately) traces behind.

Of particular interest are artifacts created as a side effect of the user's web browsing activities. Browsers routinely retain a large amount of cached information about its users' online life—history, searches, bookmarks, cookies, screenshots, open tabs, etc. As Altheide describes in detail [Alth11], most of these data are now stored in common data formats, which makes it trivial to recover and interpret.

Another rich source of information is the metadata that are routinely embedded in various artifacts, such as author information and version information in office documents, and camera and GPS information in image data.

Beverly et al. [Beve11] demonstrated that the average disk contains a significant number of IP and MAC addresses that can be extracted by means of carving and validation. In a sample of 723 hard drives, they found an average of 2279 IP addresses. In addition to the obvious use of connecting a drive to a network, the addresses could be used via geolocation services to map the physical location of a target machine.

Cohen et al. [Cohe11] provide a different perspective on forensics—one in which security monitoring, incident response, and forensic tool are put together in a large distributed system to keep Google's expansive IT infrastructure secure. In building a distributed system to perform these tasks, a number of conflicting requirements, such as performance, privacy, and network connectivity, lead to technical solutions that would be considered incomplete in a classical forensic investigation.

56.4.2 Memory Forensics

The original view of best forensic practices (from a decade ago) was to literally pull the plug on a machine that is to be impounded. The rationale was that this removes any possibility to alert processes running on the host and would preempt any attempts to hide information. Over time, however, experience showed that such concerns were overblown and that the substantial and irreversible loss of important forensic information is simply not justified.

Memory analysis can be performed either in real-time on a live (running) system, or it could be performed on a snapshot (memory dump) of the state of the system. In live forensics, a trusted agent (process) designed to allow remote access over a secure channel is pre-installed on the system. The remote operator has full control over the monitored system and can take snapshots of specific processes, or the entire system. By and large, live investigations are an extension of regular security preventive mechanisms, which allows for maximum control and data acquisition. However, such mechanisms need to be pre-installed, which is only practical in commercial and government entities that can afford the expense of maintaining such a system.

In the general case, memory forensics reduces to forensics of a snapshot (a.k.a. *dead* forensics). It should be evident that analyzing a snapshot is considerably more difficult because we lack the run-time facilities and context provided by the live operating system. We need fundamentally new tools that can rebuild as much as possible of the state of the running system in a forensically sound manner, and, therefore, such tools are the main point of discussion for the rest of this section.

56.4.2.1 Memory Acquisition

Studies have illustrated that data persist for a long time in volatile memory ([Chow04], [Solo07]). Unlike tools that analyze running machines, off-line memory analysis tools extract digital evidence directly from physical memory dumps. These memory dumps may be acquired using a number of different mechanisms (dependent on operating system type and version), from hardware-based approaches, such as Tribble [Carr04] and via the Firewire interface [Bock], to software-only approaches [Vida06], such as using *dd* to access the physical memory device or via insertion of custom kernel modules. Vomel [Vome11] provides a comprehensive survey of modern acquisition techniques.

These memory dumping mechanisms are not infallible and some high-tech approaches to subverting memory acquisition have been proposed [Rutk07]. Fortunately, unless the subversion mechanism is very deeply embedded in the operating system, a substantial amount of overhead may be incurred to prevent acquisition, potentially revealing the presence of a malicious agent [Korn06a, Korn07]. Ruff and Suiche [Ruff07] developed a tool that provides another alternative for memory acquisition, by converting Windows hibernation files to usable memory dumps. Schatz proposed a novel approach to memory acquisition technique called BodySnatcher, which injects a small, forensic operating system that subverts the running operating system [Scha07]. Sylve's work [Sylv12] on Android memory acquisition* developed ostensibly for mobile devices works equally well on traditional Linux deployments.

Once obtained, a RAM capture contains a wealth of information about the run-time state of the system, with the most important listed in the following:

- *Process information*: We can enumerate and identify all running processes and threads and their parent/child relationships; we can enumerate all loaded systems modules, and can obtain a copy of the processes' code, stack, heap, code, and data segments. All of this information is particularly useful in analyzing compromised machines as it allows us identify suspicious services, abnormal parent/child relationships, and to scan for known malicious code.
- *File information*: We can identify all open files, shared libraries, shared memory, and anonymously mapped memory. This is useful for identifying correlated user actions and file system activities and to prove more difficult implications, such as user intent.
- *Network connections*: We can identify open and recently closed network connections, protocol information, as well as send and receive queues of data not yet sent or delivered, respectively. This information could readily be used to identify related parties and communication patterns among them.
- *Artifacts and fragments*: Just like the file system, memory management systems tend to be reactive and leave a lot of artifact traces behind. This is primarily an effort to avoid any processing that is not absolutely necessary for the functioning of the system. As well, caching of disk and network data can leave traces in memory for a long time.

* http://www.digitalforensicssolutions.com/lime/

56.4.2.2 Memory Analysis

The 2005 DFRWS memory analysis challenge* has served as an early catalyst to push the development of tools for Windows memory forensics and resulted in several early projects.

K*nTTools*† extracts information about processes, threads, access tokens, the handle table, and other operating system structures from a Windows memory dump. The *memparser*‡ tool has the added ability to detect hidden objects by cross-referencing different kernel data structures. Schuster's *ptfinder* tools ([Schu06a], [Schu06b]) take a different approach: instead of walking operating system structures, they attempt to carve objects that represent threads and processes directly. Noting the relative dearth of usable tools for deep parsing of Linux memory captures, DFRWS created its 2008 challenge [Geig08] with a major emphasis on Linux memory forensics. Prior to that, the most notable work is Burdach's [Burd] proof-of-concept tool called *idetect*, which parses kernel 2.4-series memory dumps and enumerates page frames, discovers user mode processes, and provides detailed information about process descriptors. Case et al. [Case10] demonstrated the most advance memory parsing techniques, which allows their tool, *ramparser*, to find kernel structures even in custom Linux distributions, which are very common on various devices.

The most influential project in memory forensic has been the development of Volatility Framework§ led by Aaron Walters [Petr06, Walt07]. It provides core memory processing capabilities for Windows-based systems and a component architecture that allows third-party expansion. Volatility supports multiple input formats (raw, hibernation file, crash dump), and can extract running processes, loaded module, open network connections, open registry items, reconstruct executable binaries, and automatically map virtual to physical addresses. The project has become the focal point for most recent research and development efforts in memory forensics and has the potential to bring all practical techniques into a single package.

56.4.3 Network Forensics

Network forensics uses specialized methods to collect, record, and analyze transmitted data for the purposes of detecting or reconstructing a sequence of relevant events. Obviously, the main source of information is network traffic, which may be monitored in real time, or recorded and analyzed later. From the point of view of forensic reconstruction, there is no fundamental difference between the two cases and the same methods could be applied (subject to performance constraints). Most network traffic analysis is preventive monitoring and aims to identify and neutralize security threats in real time—firewalls and intrusion detection systems observe and actively manipulate network flows to achieve the desired security posture.

It can be useful to distinguish two types of network inquiries—incident response and forensic reconstruction—although they often blend together. Incident response teams deal with identified security breaches, and they function much like an emergency room team—quickly assess the immediate damage, stop the bleeding, and commence a recovery operation. Forensic reconstruction is a deeper analytical process to put together the sequence of events that lead to the incident, assess the wider scope of damages—which systems were compromised and what data were compromised—and try to attribute blame to the ultimate source of the attack.

56.4.3.1 Capture and Reassembly

Among general-purpose network capture and analysis tools, Wireshark¶ (a.k.a. Ethereal before 2006) stands out as the most popular and complete one in the public domain. It can analyze both live

¶ http://wireshark.org

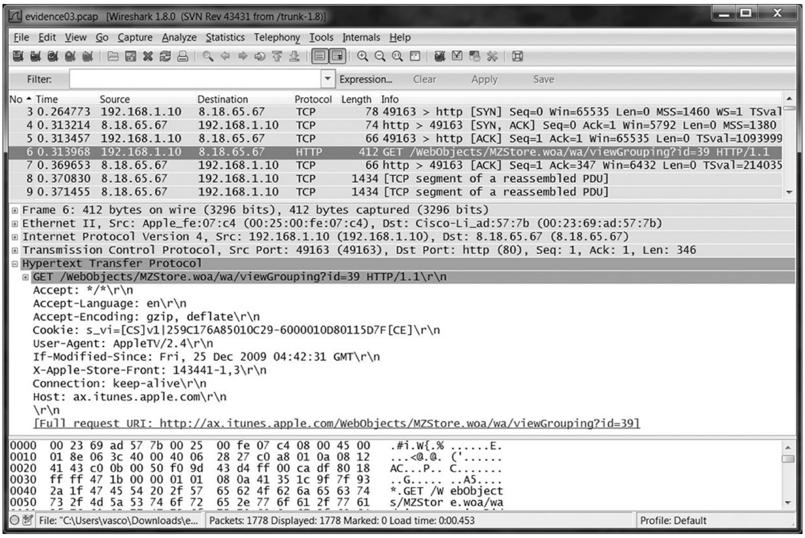

FIGURE 56.4 *Wireshark*'s main window displaying an HTTP request.

traffic and network captures. Its main interface window is shown in Figure 56.4. It consists of three components—a table of captured network packets, a detail panel showing the interpretation of the selected packet, and a raw hexadecimal/text display at the very bottom. Since the number of packets quickly becomes overwhelming, the tool provides a filtering facility, which allows for selection based on any of the fields shown—source, destination, protocol, content, etc.

Recall that the purpose of the Internet protocol stack is to provide end-to-end communication channels for distributed processes that execute on connected hosts. The data sent by processes are transformed by four different layers—application, transport, network, and data link—each of which leaves its footprint on the observed traffic. In particular, the flow of data sent is split into protocol data units and each layer adds protocol-specific header to the original message. During transmission, pieces from different connections are interleaved, which leads to the need to reconstruct the entire conversations to make sense of them; Figure 56.5 shows an example of a reconstructed conversation between a web client and server.

56.4.3.2 Analysis

Network data analysis follows the earlier mentioned process and can be performed at the four different layers of abstraction, depending on the focus of the investigation. At the transport layer, the most important pieces of information added in the header are the source and destination port numbers, which locally identify the communicating processes at the sender and the receiver, respectively. The network layer header contains, among other things, the source and destination IP addresses, which identify the sending and receiving hosts. Finally, at the data link layer, the header contains the physical (MAC) addresses of the source and destination for the current hop on the LAN. For every hop, that information will be different as different hosts, using potentially different link types (Ethernet, 802.11, FDDI) will be forwarding the data.

Thus, if a case revolves around a wireless network breach, the most relevant data are likely to be found at the data link layer. If the issue is a botnet attack coming from the Internet, then most of the relevant data will probably be in the network and transport layers. If the problem is data ex-filtration, the best starting point is likely to be the application layer, as a user is likely to use a ready network application, like email, to transmit the data.

Automating the process of network forensics is an ongoing challenge; the sheer volume of data means that, in order to find the artifacts of interest, one needs to know rather specifically what to look for.

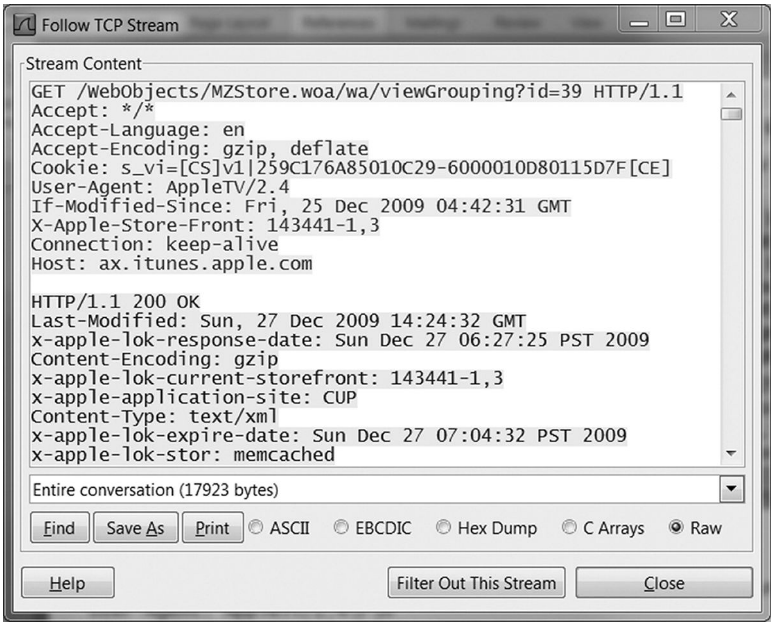

FIGURE 56.5 Reconstructed HTTP client/server conversation in *Wireshark*.

Most network monitoring tools, such as NetWitness,* provide rule-based filtering and aggregation and can alert an analyst that something is amiss. For example, an increase in malformed packets, or abnormal levels of traffic could be an indication of an attack attempt, as would be connections on unusual for the advertised protocol port, connection attempts to known bad hosts, obfuscated content, etc.

56.5 Artifact Analysis

Another approach to understand forensic processing is to consider different methods for processing digital artifacts. We can take advantage of the fact that the representation of many artifacts—text, images, audio, video—remains consistent across different media and devices and we could develop generic methods that could be applied across the board.

56.5.1 Crypto Hashing

The lowest common denominator for all digital artifacts is to consider them a sequence of bits/bytes without trying to parse them, or assign any meaning. Despite this low level of abstraction, there are some very important problems that can be addressed and the most important one of them is to find known content.

Hashing is the first tool of choice in investigating any case, as it provides the reliable means to validate data integrity and to identify known content. At a basic level, hash-based methods are attractive due to their high throughput and memory efficiency. Recall that a hash function takes an arbitrary string of binary data and produces a number, often referred to as digest, in a predefined range. Ideally, given a set of different inputs, the hash function will map them to different outputs.

Hash functions are collision-resistant if it is computationally infeasible to find two different inputs for which the output is the same. Cryptographic hash functions, such as MD5, RIPEMD-160, SHA-1, SHA-256, and SHA-512, are explicitly designed to be collision-resistant and to produce large, 128- to 512-bit results.

* http://www.netwitness.com/

Since the probability that two different data objects will produce the same digest by chance is astronomically small, we can assume that, if two objects have the same digest, then the objects themselves are identical.

The current state-of-the-practice is to apply a cryptographic hash function, typically MD5 or SHA-1, either to the entire target (drive, partition, etc.) or to individual files. The former approach is used to validate the integrity of the forensic target by comparing before-and-after results at important points in the investigation. The latter method is used to eliminate known files, such as operating system and application installations, or to identify known files of interest, such as illegal ones. The National Institute of Standards and Technology (NIST) maintains the National Software Reference Library,* which covers the most common operating system installation and application packages. Similarly, commercial vendors of digital forensic tools provide additional hash sets of other known data.

From a performance perspective, hash-based file filtering is very attractive—using a 20-byte SHA-1 hash, we could represent 50 million files in 1 GB. Thus, we could easily load a reference set of that size in main memory and filter out, on the fly, any known files in the set as we read the data from a forensic target. In addition to whole files, we are often interested in discovering file remnants, such as the ones produced when a file is marked as deleted and subsequently partially overwritten.

One routinely used method to address this problem is to increase the granularity of the hashes—we can split up the files into fixed-size blocks and remember the hashes for each individual block. Once we have a block-based reference set, we could view a forensic target as merely a sequence of blocks that can be read sequentially, hashed, and compared to the reference set. Typically, the block size is 4 KB to match the minimum allocation unit used by most operating systems installations. There are two main advantages to this scheme—we can easily identify pieces of known files and avoid reading the target hard drive on a file-by-file basis [Garf10].

56.5.2 Approximate Matching

So far we looked at ways to find artifacts that are identical; however, we could consider the more general problem of finding objects that have similar binary representation. Inspired by earlier work in spam filtering, Kornblum [Korn06b] proposed a fuzzy hash construction. It uses shingling to split up the file into chunks; generates small, 6-bit hashes for every chunk; and concatenates them to produce the final hash, which is base64-encoded. This scheme is a derivative of Rabin's groundbreaking work on data fingerprinting by random polynomials [Rabi81]. For the similarity comparison, the two hashes are treated as text strings and are compared using an edit distance measure, which produces a number between 0 and 100.

An interesting design choice is to limit the overall size of the hash to 80 symbols—this is mainly driven by the aim to give investigators a fixed hash value per file similar to the ones produced by crypto hashes (MD5, SHA-1, etc.). To achieve this, the algorithm uses the file length to estimate the number of piece it needs to break the file into. After the hash calculation is completed, if the result is longer than the target 80 symbols, the estimate is doubled and the calculation is redone from scratch. Due to its sensitivity to object size, the actual file signature produces two hashes for two different resolutions—c and $2c$. This takes the edge off the problem; but if the difference in size between the data objects exceeds a factor of four, the two are not comparable. In practice, the hash does seem to work well in identifying objects that are versions of each other and are not too big and not too dissimilar; however, the hash quickly loses resolution for larger files and cannot be applied to stream data where size is unknown.

Roussev et al. [Rous06] proposed a similarity hash measure, primarily targeted at detecting versions of executable files and libraries. The essential idea is to break up the object into known constituent parts (coded functions and resources), hash each one individually, and combine them into a Bloom filter to produce the similarity hash. Hashes are then compared by counting the number of corresponding

* http://www.nsrl.nist.gov

bits in common between the two filters and comparing them with the theoretical expectations—any statistically significant deviation is an indication of similarity. Performance results for system libraries demonstrate that versions are readily detectable by this method, even when filters with very high compression rates are used.

The follow-up work on multi-resolution similarity (MRS) hashing [Rous07] addressed the problem of comparing objects with vastly different size, such as a file and an entire drive. To balance the requirements of accuracy and performance, it was proposed to generate similarity hashes at multiple levels of resolution and to choose an appropriate level, depending on the specific objects being compared.

In [Rous10] Roussev proposed a new approach to generating similarity data fingerprints based on the idea of statistically improbable features. In essence, from every neighborhood the scheme selects a few 64-byte features (byte sequences) that, based on a statistical survey, are least likely to appear by chance. The method relies on the calculation of the Shannon entropy of each sequence and has the added advantage that low-entropy features likely to trigger false positive results are eliminated. This is a different approach from the random polynomials, and the user study in [Rous11] clearly demonstrates that: (a) the approach performs better than random polynomial as low-entropy data are eliminated from consideration; (b) the bit stream similarities found almost always correspond to user observable similarity. Overall precision and recall rates were in the 95% range. Subsequent work further developed the concept to allow parallel computation of the digests [Rous12a] and applied similarity digests as a primary triage technique to a 1.5 TB case study [Rous12b] with over 120 different data sources.

56.5.3 Multimedia

The ability to attribute a multimedia artifact to its source, as well as the ability to identify forged artifacts, is of critical importance to a forensic investigation. Our discussion is focused on images, but similar concerns and methods apply to audio and video artifacts. The problem matching an image and its camera source has been approached from two perspectives: (1) identify the type of camera that has taken this photograph; or (2) prove that the image has been produced by a specific camera.

In [Fang09], the researchers introduce a forensic scheme to distinguish between DSLR and compact images. Since DSLR and compact cameras use different type of sensors and lenses, their camera output quality in terms of sharpness and ISO sensitivity differs significantly. Such differences also affect the sensor noise levels and can be detected through wavelet decomposition and noise analysis. The experimental results show that the proposed forensic scheme has a potential to identify DSLR and compact images even when they are recompressed or down-sampled by 50%.

Lukas et al. [Luka06] proposed a method for identifying the source camera of a digital image based on the imaging sensor's noise pattern. The pattern is extracted by considering a large sample of the images from the camera, and the attribution of images is performed through statistical correlation. To improve the applicability of the method as a forensic tool, Sutcu et al. [Sutc07] proposed an enhancement based on artifacts produced by the demosaicing operation (color interpolation performed by the color filter array of the camera).

Sophisticated image manipulation has become a commodity technology, and it is becoming near impossible to spot forgeries simply by looking at the image. Farid has an excellent survey [Fari09] on the various techniques that could be applied to detect forgery. Here, we offer a brief summary of the different classes of techniques.

Pixel-based techniques work by analyzing the image to detect the most common types of image tampering like cloning, resampling, and splicing. In all cases, the basic observation is that, although the image is perceptually sound, the underlying transformation creates detectable artifacts that can be exposed and detected via statistical classification.

Format-based technique works by considering the effects of lossy image compression, such as the popular JPEG, on the image. Namely, the image is encoded based on a lattice of 8×8 blocks, and the DCT coefficients of the block are quantized and encoded. This process is the main source of loss and produces (not always visible) artifacts along the boundaries. These can be used to detect various forms of tampering.

Camera-based techniques can identify the fact that different pieces of the image do not come from the same camera and this could be established using the attribution techniques outlined earlier. Another technique to spot manipulated images is to consider lighting—it is quite difficult to have two photographs taken under the exactly same conditions. By analyzing the direction from which the light shines on different objects [John 05], it is practical to determine that the image is a composite. For human subjects, the eyes provide a perfect point of reference as their high reflectivity often provides a clear indication of the positions of light sources.

Geometry provides another approach for detecting image tampering. In authentic images, the projection of the camera center onto the image plane is near the center of the image. When a person or object is translated in the image, the principal point is moved proportionally, so any differences in the estimated principal point across the image can be used to detect tampering. In [John07], Johnson and Farid apply this idea of using a pair of eyes, or other suitable objects, to estimate the camera's principal point from the image.

56.5.4 Event/Timeline Reconstruction

Timelines are one of the most frequently used tools in forensic analysis. Typical data sources, like the file system, provide generous amounts of timing information as every creation, access, or modification to a file leads to update of their MAC (modification/access/creation) timestamp attributes. The three main problems related to timelines are provenance, synchronization, and visualization.

The problem of establishing the provenance and reliability of timing information found on a target stems from the fact that timestamps carry no special protection and could be manipulated by users. Users with root access can modify the system clock or manipulate any timestamp directly. Even if no tampering is done, establishing the order of events taken place on the Internet is not as easy as it may appear—no two hardware clocks advance at the same rate, which means that they tend to drift away from real-world time and from each other.

Most hosts use NTP to periodically synchronize with time servers and, thereby, limit the amount of drift. Yet, the error is always present and is complicated by misconfigured clients and servers. Time zones, differences in time-keeping methods on different platforms, and "clock" events like daylight savings time, which are applied very unevenly around the world, further complicate efforts to establish the order and timing of events. In 2007, Buchholz [Buch07] performed a sizeable survey of computer clocks on the Internet and documented these pathologies using a large amount of empirical data.

Forensic timeline visualization tools have considered different approaches to aggregating the timing information—from lower to higher level event and displaying it to the examiner. On the left, Figure 56.6 shows the approach taken by Zeitline [Buch05]—one of the early systems. The essential idea is that investigators can go over the ordered list of events and create different timelines related to different aspects of the investigation. They can also group low-level events and annotate them as higher-level events, ultimately building a hierarchy out of the flat timing information.

TimeLab [Olss09] takes a more automated approach—it uses a number of specialized scanners to process different sources of timing information both from artifact metadata and from system logs. It displays the different timelines next to each other and has basic facilities to zoom in and out to refine granularity of the display.

The *log2timeline* tool [Gu10] is the most comprehensive timeline extraction tool used by practitioners—it parses everything from file time stamps and event logs to registry entries and browser artifacts. It can quickly produce a large amount of data, even for a modest data source. The challenge for the investigator

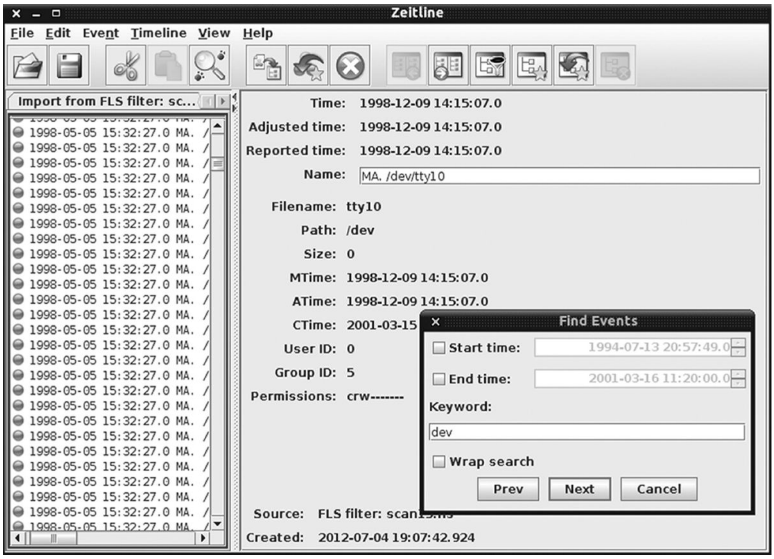

FIGURE 56.6 Forensic timeline visualization with *Zeitline*.

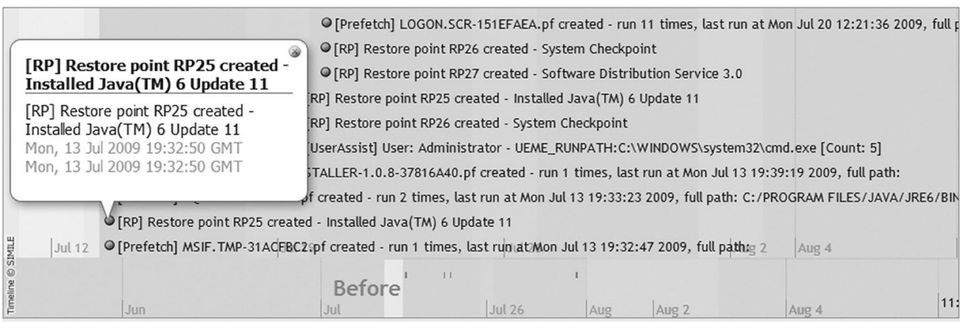

FIGURE 56.7 Visualization of a timeline produced by *log2timeline* using *SIMILE Timeline*.

is soft through, which is typically performed by custom scripts. The visualization is treated as a separate concern and can be performed with general timeline tools like SIMILE Timeline widget* to provide a more intuitive navigation (Figure 56.7) and exploration.

56.5.5 Application Forensics

Application forensics refers to the process of reliably establishing the behavior of applications as the result of user actions, and the identification of associated artifacts. Once such causal links are established, we can look for the artifacts to infer user behavior. As the name suggests, application forensics is inherently tied to the piece of software being used, and it is difficult to generalize this work across applications.

One prominent example of frequently used application forensic analysis is peer-to-peer (P2P) networks. Despite its numerous legitimate uses, P2P has also gained notoriety as one of the major means of distributed contraband material, as well as a major source of copyright infringement complaints. At first glance, one could be tempted to classify this as a network forensics problem. However, a closer look at the methods used

* http://www.simile-widgets.org/timeline/

reveals that no actual analysis of network traffic is performed. Since the purpose of P2P is file sharing, it is much easier to handle the problem on the end system by examining the artifacts from the P2P interactions.

P2P Marshal [Adel09] is a tool which automatically detects and analyzes P2P client use found on a particular target machine. The tool aims to automate end-to-end the process of investigating a target for all known P2P activity. It determines what clients are currently installed (or have been installed) on a machine, and then extracts per-user usage information for each client, including lists of shared or downloaded files and peer-servers contacted. Throughout the process, the tool performs its actions in a forensically sound way and maintains a detailed log of all actions performed.

Liberatore et al. [Libe10] provide a more general technical and legal context for investigating P2P networks. Specifically, they study the problem of identifying and tracking individual users in Gnutella and BitTorent and show the problems arising from hearsay information distributed through the networks.

56.6 Forensic Tool Design and Implementation

From a historical perspective, computer forensics tools are relatively young in their development cycle. At this stage, several commercial vendors have established strong presence in forensic labs by providing integrated investigative environments that attempt to support the complete inquiry cycle from acquisition to reporting. Not surprisingly, these vendors would like to retain their competitive advantage. To achieve this, they have created a "walled garden" environment, trying to lock in clients and to establish their standards as the de facto standards for the community.

Much of the advanced research in forensics is produced in academia, which simply lacks the incentives and the resources to develop fully functional integrated environments. Instead, researchers tend to focus their effort on a specific problem and to produce a narrowly targeted tool, which often requires climbing a learning curve before it can be put into practical use. Based on the experience of more mature software domains, the above situation is typical—commercial tools in the field are ready for practical use, but rarely employ the most advanced techniques.

The grand challenge for forensic tool design is to build tools that closely match the cognitive task of forensic analysis. Current generation tools are squarely focused on the information foraging loop (Figure 56.1). Specifically, they emphasize the gathering part of the loop, with most of triage and filtering functions primarily performed by the analyst.

56.6.1 Scalability and Automation

The need for scalable distributed forensic processing was first identified by Roussev and Richard [Rous04, Rich06] as a critical issue that forensic tools will face. Indeed, increasing data volume is already taxing existing systems to the point where slow performance is becoming one of the top concerns for investigators [Hibs11], along with the need for smarter and more automated tools. Coincidentally, more automation and smarter tools also imply more processing, specifically more *compute-intensive* processing. Thus, building *scalable* tools that can handle large cases is a problem of crucial necessity.

The efforts so far have been relatively few despite the early work in [Rous04], which showed that even a modest research prototype can speed processing considerably; in some cases, super-linear speed up has been observed due to cumulative caching benefits. In [Rous09], another research prototype showed the suitability of Map-Reduce style for forensic processing by quantifying its performance on a small cluster using a custom map-reduce system.

56.6.2 Standards and Inter-Operability

Given the wide range of possible forensic analysis tasks, it is difficult to conceive that any particular integrated product would cover everything. Therefore, it is in the interest of the community at large to develop standards that allow for interoperability among tools.

The push for standards has been around for a number of years and has had some high-profile backers, such as the National Institute of Justice, which supported the development of the Digital Evidence Markup Language (DEML). It appears, however, that this effort to define a comprehensive standardized description standard has gained little traction and has all but disappeared into obscurity.

In the real world of forensics, the most pressing concern is the storage of real evidence sources. For some time, the de facto standard for digital evidence containers has been the Expert Witness Format (EWF) developed and maintained by Guidance Software—the maker of the EnCase Forensic product. This is a proprietary format, which has been thoroughly researched and reverse-engineered by the makers of libewf*—an open source library for manipulating EWF containers.

A strong, open alternative has been the afflib project,† which produced the Advanced Forensic Format (AFF) [Garf, Garf06] that, from a purely technical design perspective, is more advanced and forward looking than EWF [Cohe09]. A number of efforts have centered on the idea of using XML containers for digital evidence, most notably XIRAF [Alin06] developed the Netherlands Forensic Institute, and DEX [Levi09] from the University of Massachusetts. The main drawback of using XML is that it is quite verbose and inefficient for the large amounts of data that need to be stored for every case. To become a practical alternative, an XML-based scheme must incorporate compressed storage without compromising the inherent query advantages of XML containers—a non-trivial design challenge.

With the recent push toward the use of memory forensics methods, the need has emerged to define a suitable container format for imaged memory targets. Schuster [Schu08] has commenced an effort to adopt an early standard for such evidence.

The most comprehensive and mature research and development effort is the courtesy of Simson Garfinkel [Garf12]. The Digital Forensics XML (DFXML) is an XML language that enables the exchange of structured forensic information. DFXML provides the means to comprehensively describe any piece of data relevant to an investigation—volumes, files, registry entries, etc.—and maintains provenance information.

56.6.3 Tool Testing and Calibration

One fundamental difference between forensic tools and most other tools is that the legal system and the society at large must be able to trust the results of a forensic inquiry. For that purpose, each tool should be tested and its performance and error rate thoroughly documented. In practice, only simple tools, such as data cloning ones, have been independently tested and this remains a major challenge for researchers and developers.

One of the most important research efforts is the establishment of representative public data sets that can be used for research and testing. This requires a significant effort in any discipline, but forensics presents at least three added challenges: (1) the actual data on which investigations are performed cannot be published; (2) each case is different, so establishing a representative set requires a huge amount of data gathering; (3) we have no credible methods of generating simulated data, especially for complex scenarios.

The DFRWS conference (dfrws.org), through its annual challenges, has contributed several data sets that are often used as benchmarks in evaluating file carving and memory analysis tools. Garfinkel et al. [Garf09] have collected and published several important data sets, such as the *real data corpus* (U.S. and non-U.S. sets), which consists of used drives obtained on the secondary market (6.7 TB), the *govdocs* corpus (1 TB), which consists of a million copyright-free U.S. government documents, and the M57 corpora (1.5 TB), which consists of the data collected during a scripted exercise on a private network.

56.7 Summary

In this chapter we presented a brief overview of the state of the art and state of the practice in digital forensics. Within the constraints of a single chapter, the primary goal has been to provide broad conceptual coverage of this growing research field as opposed to in-depth discussion of specifics.

As a computer science discipline, digital forensics is a smaller and younger field relative to the broader area of security and privacy. Its *initial* development was somewhat ad hoc as it was driven by the daily needs of forensic examiners who did not necessarily have in-depth technical knowledge and had to learn on the job. Over the past decade, however, a growing number of computer science researchers have entered the field and have made progress in establishing more rigorous scientific approach to the development and testing of digital forensic methods.

Researchers and practitioners have developed a large number of specialized methods to identify, extract, and forensically analyze digital artifacts that are resident in main memory, stored on secondary storage, or transmitted over the network.

The foreseeable future promises to continue to bring exponential growth in forensic data, and increasingly complex processing due to the growing number of applications and devices, and their interactions. Increasingly, the type of deep analysis where a human investigator sifts manually through large amounts of data will become infeasible.

56.8 Open Issues and Challenges

Looking forward, digital forensics faces new challenges as new technologies continue to enter our lives. Every new technology presents new challenges and increases the complexity of the forensic analysis, and an exhaustive list of upcoming challenges could be quite long. Therefore, we chose the ones we consider the most fundamental.

56.8.1 Scalability and Automation

Looking forward, the biggest challenge looming over forensics is the ever growing mountain of data that our society produces. FBI statistics show that between 2003 and 2010, the average amount of data per case has grown from 80 to 470 GB—an average annual growth rate of 28%. Such growth, along with technology trends in computing, storage, and communication, renders current single-machine approaches to investigation unsustainable. Forensic computing needs to be able to employ as many resources as necessary to keep pace with the needs of society. To answer the challenge, researchers need to develop new methods that allow for effective automated data reduction, massive parallel processing, and efficient collaboration among investigators.

56.8.2 Sensor and Device Diversity

Another important direction in technology development is the proliferation of various sensors and devices, which drive us toward a pervasive computing environment. Even defining the scope of an examination will become increasingly more difficult as the interconnections among the components open up a large number of potential lines of inquiry. Our current abilities to quickly investigate new devices are quite modest and predominantly focused on mobile phones.

56.8.3 Virtualization and Cloud Computing

Existing methods and procedures are closely tied to the hardware of the investigated system. It is clear that virtualization technology, which decouples a computation from its hardware platform, has become a commodity and will become pervasive in the next few years. Cloud computing is a natural progression

of the virtualization idea, and it allows the computation to move the place in the network where it is most efficient to execute.

This is a fundamental change as it negates one of the fundamental assumptions in forensics—that a process is tied to its hardware. Other important consequences include the fact that virtualization means sharing of the same of same physical resources—memory, storage—by numerous, unrelated computations. This forces the infrastructure to sanitize all resources after use and eliminates a vast amount of evidence currently in use.

56.8.4 Pervasive Encryption

Expanding on the previous point, for a long time we have relied on fact that data on most media are readily accessible—encryption was always an option, but the cost was generally too high for most applications. The default state of affairs is about to change—encrypted data is becoming the norm with the introduction of hardware encryption on hard drives. Due to privacy concerns on cloud computing, it is not difficult to envision encryption becoming the norm for in-memory data.

So far, forensic investigators have relied on implementation flaws to get around the encryption problem; however, sooner rather than later, encryption implementations will be cleaned up and the data would be truly inaccessible. Indeed, proper use of encryption should make it inaccessible and there are powerful economic and societal interests that will push for getting it right.

56.8.5 Legal Issues and Proactive Forensics

As better security and privacy mechanisms are deployed ubiquitously, it is increasingly likely that a number of staple forensic techniques would drop in significance. In particular, it is reasonable to expect that operating systems and applications will be more careful about "shredding" de-allocated objects, thereby eliminating traces upon which we currently rely. The trend toward more network-centric cloud computing means that a number of legal issues, such as location of the data, can further reduce the available forensic data.

This leads us to the conclusion that more and more forensically relevant data would have to be collected *pro-actively*, as already suggested by Shields [Shie11] and as already practiced by many large organizations as part of routine monitoring. Further expansion of this data collection will likely require a proper legal framework. What shape this may take is beyond the scope of this chapter but it is fair to say that, currently, the legal system lags considerably behind the pace of technology development and has been in no rush to catch up.

Glossary

Cryptographic hash: A deterministic algorithm that takes an arbitrary block of data and returns a fixed-size bit string, such that *any* change to the data will change the hash value.

Digital/electronic evidence: Probative information stored or transmitted in digital form that can be used in legal proceedings.

File/data carving: The process of extracting and reconstructing digital artifacts from constituent pieces.

Forensic timeline: A sequence of user- and system-initiated events deduced from available time information from sources like logs, file metadata, and file system metadata.

Live forensics: The application of forensic methods to examine the state of a running system.

Memory forensics: The process of reconstructing the live state of the system from a snapshot of RAM contents.

Network forensics: The process of reconstructing the history and content of communication between devices of interest.

Provenance of digital evidence: An explicit description of the set of tools and transformations that led from acquired raw data to the resulting conclusion.

Secure deletion: The process of overwriting de-allocated artifacts such that subsequent reconstruction is not possible.

Similarity/fuzzy hash: A hash function that maps syntactically similar artifact to numerical values that are close to each other.

Managing Organizational Information Systems and Technology Capabilities

57

Organizing and Configuring the IT Function

Till J. Winkler
Copenhagen Business School

Carol V. Brown
Stevens Institute of Technology

57.1 Introduction

How to organize and configure the internal information technology (IT) function* has been a critical issue since the beginning of enterprise computing. One of the most important challenges in IT organization design is selecting the extent to which IT decision-making and IT resources (including the IT workforce) are centralized (Brown and Magill 1994). The key rationale for centralization is to leverage economies of scale; the underlying rationale for decentralization is to ensure local responsiveness to internal and external customers (Sambamurthy and Zmud 1999; Agarwal and Sambamurthy 2002; Weill and Ross 2004).

Over the past decades, IT organizations have oscillated between centralized and decentralized forms (Peak and Azadmanesh 1997; Evaristo et al. 2005). In the beginning of enterprise data processing, mainframe computers and magnetic tape devices were commonly organized in central data centers. After the late 1980s and the vast growth of distributed computing (Von Simson 1990), client-server and firm-wide enterprise resource planning applications led to IT recentralizations (Brown 2003; McAdam and Galloway 2005). Many firms further consolidated large parts of their IT infrastructure and application operations into independent shared services organizations (Evaristo et al. 2005). These serve several lines of business to gain further economies of scale advantages as well as to improve the quality of overall IT service delivery through introducing standard IT practices (Schulz et al. 2009). While recent IT reference frameworks—such as ITIL, ISO/IEC20000, CMMI, and COBIT—provide some guidance for designing the IT function and internal processes (Pardo 2010; Marrone and Kolbe 2011), this chapter takes an enterprise-level perspective.

* The terms information systems (IS) and information technology (IT) are both used in the literature to describe the IS/IT organization and IS/IT function. In this chapter we will use the term "IT" when referring to an organizational unit performing all or some of the IT functions within an enterprise.

In this chapter we present four IT organization archetypes that differ based on the centralization versus decentralization of both (1) IT decision rights and (2) allocated IT resources. We describe these archetypes based on four additional design dimensions: (1) coordination mechanisms, (2) financial autonomy, (3) sourcing arrangements, and (4) IT-related capabilities and skills. Being mindful that in the past the form of organizing the IT function has been heavily dependent on technological development. We predict that recent technology trends, such as cloud computing and the consumerization of IT, are likely to affect IT organization designs of the near future.

57.2 Six Dimensions of IT Organization Configurations

Organizations (profit as well as non-profit) typically consist of multiple units that may represent different functions or departments, lines of business, markets, or geographies (Daft 2009). We use the term "IT organization" to refer to the collectivity of human resources that perform IT-related tasks, such as planning, building, and operating IT applications and their underlying computer and communications infrastructures, as well as their relationships, practices, norms, and capabilities. This definition does not restrict the notion of an IT organization to the existence of a single organizational unit (i.e., "the IT department"). Rather, it offers the possibility to assume different design options for different IT units, depending on the needs and capabilities of the business unit(s) being supported. We also propose that six important dimensions distinguish an IT organizational design, as described later.*

57.2.1 Allocation of IT Decision Rights

According to IT governance theory, decisions on IT can be made in a more centralized or decentralized fashion (Brown and Grant 2005). In a corporate setting, centralization typically refers to allocating decision-making at the corporate level, while decentralization refers to decision authority at the divisional level or even lower organizational levels (Brown and Magill 1994). A simple scheme includes two primary decision areas: IT applications and IT infrastructure operations. A widely adopted pattern in which infrastructure decisions are centralized, but business application decisions are primarily made by the divisions, has been commonly termed a federated or *federal* model (Sambamurthy and Zmud 1999). More recently, Weill and Ross (2004, p. 6) proposed a five-part classification scheme that distinguishes decisions about business application needs, IT investment and prioritization, IT architecture, IT infrastructure strategies, as well as overall IT principles, with different patterns associated with different business priorities. Defining accountability and the sharing of decision rights between the two extreme poles of centralization and decentralization is commonly seen as a key challenge. However, some studies have demonstrated that companies with well-balanced IT decision rights exhibit better business–IT alignment and thus ultimately achieve superior firm performance (Weill and Ross 2004, p. 202). An IT reference framework such as COBIT can be used to apply overarching accountability schemes to the design of decision rights on the activity and role level.

57.2.2 Allocation of IT Resources

The second dimension captures the structural aspects of the IT organization, i.e., the position and location of the IT human and technology resources within the wider enterprise. Although some prior literature has implied that IT decision rights and IT resources reside together in an organization—we argue that these two dimensions should be considered separately (Boynton et al. 1992; Brown and Grant 2005). For example, IT decisions may be made in a decentralized manner by business units, while

* As the focus of this chapter is on organization structure, we refrain from an in-depth discussion of IT processes. However, we will make reference to process-based IT reference frameworks where suitable (see also Chapter 59 in this Volume).

IT resources operate under either divisional or corporate IT authority. Similarly, IT staff may be allocated to a line organization, but these IT resources implement services under centralized authority.

IT resource allocations have also been categorized as either IT *demand* or *IT supply* resources (Thiadens 2005, Mark and Rau 2006). That is, divisional IT units may plan for and formulate the IT resource demand for IT services at a division or business unit level, although a central IT unit (or an external supplier) may have responsibility for actually "supplying" the IT services to meet the specific business demand. Demand activities for IT operations, for example, include monitoring the delivery of IT services and issuing requests for minor changes to the infrastructure. Demand activities for IT application development include business process analysis, requirements definition, and user acceptance testing, as well as overall IT project management and steering. Although the focus of reference frameworks such as ITIL and COBIT is standardizable IT processes for IT supply units, they can provide some guidance also for designing demand-sided IT activities. For example, ITIL defines a dedicated demand management process as a responsibility of a demand manager (reporting to an IT unit).

In practice, the degree of centralization of IT resources differs widely under different IT organization archetypes (Hitt and Brynjolfsson 1997). In highly decentralized IT organizations divisional IT units also accomplish IT supply tasks, while in very centralized IT organizations corporate IT groups also manage much of the IT demand. The distribution of resources has overall been found to reflect the extent to which companies pursue economies of scale, versus enabling local responsiveness through the allocation of resources (Brown and Magill 1994).

The first two dimensions of our framework—allocation of IT decision rights and allocation of IT resources—form the axes for the 2 × 2 matrix in Figure 57.1. In addition to the centralized and

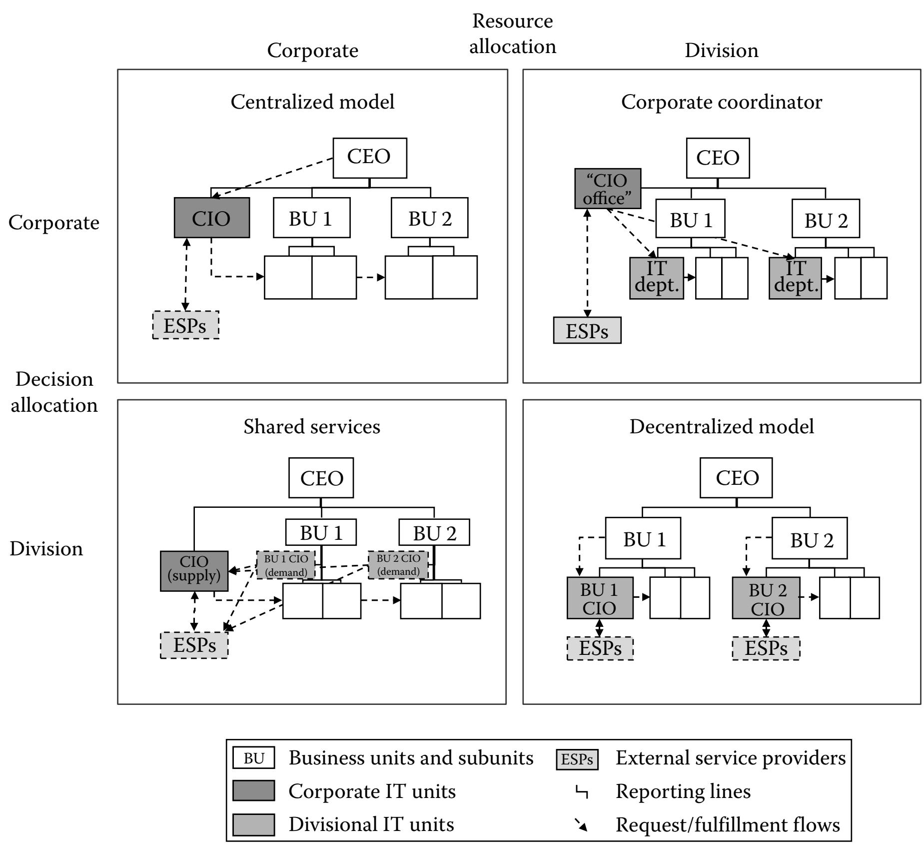

FIGURE 57.1 IT organization archetypes.

decentralized polar extremes, two other IT organization archetypes are defined. In the shared services model, IT decision rights are highly decentralized, but the IT resources that perform IT tasks are highly centralized. In the corporate coordinator model, the IT resources are highly decentralized or outsourced, but a central office holds a higher degree of IT decision rights. Four additional design dimensions for characterizing these archetypes are described later.

57.2.3 Coordination Mechanisms

The mechanisms for coordinating IT tasks across multiple organizational units—e.g., corporate functions, business units or divisions, and/or corporate and divisional IT groups—are an important complementary design dimension to the formal allocation of decision rights and resources (Brown 1999). They can be viewed as an *overlay* of the structural organization, which enables horizontal, not just vertical, information sharing (Daft 2009, p. 95). In general, the more complex and dispersed allocations of decisions and resources are, the more sophisticated coordination mechanisms need to be to effectively coordinate and integrate across the different parties involved in decision-making and execution (Peterson et al. 2000). Three categories of coordination mechanisms have been emphasized in the literature: structural mechanisms, procedural mechanisms, and relational mechanisms (Van Grembergen 2004, p. 20).

Structural mechanisms include "standing" groups or committees (in contrast to temporary teams or task forces), and formal roles that link across different organizational units. Widely used standing groups for IT governance decisions are, for example, IT steering committees with key business representation and IT management councils (Brown 1999). Formal liaison roles for IT demand management have also been implemented in many organizations within both business and IT units, e.g., account managers and business analysts reporting to IT units, as well as divisional information officers, business process owners, and key users residing in business units. Specific examples of tasks for such committees and liaison roles are now also part of common IT reference frameworks.

Procedural mechanisms are the specified rules and standard practices for decision-making and alignment between business and IT units (Peterson et al. 2000). Processes that span business and IT units include the IT strategy process, the IT budgeting and investment review process, project controlling processes, system change request and service level management procedures, etc. Naturally, both formal roles and standing groups are highly involved in effectuating procedural mechanisms. Common reference frameworks typically define a number of processes that involve these roles and groups—e.g., ITIL's demand management and service level management processes.

Relational mechanisms characterize those practices that aim to link stakeholders in different organizational entities *informally* (i.e., outside of their role description or formal responsibility). Common approaches are communities of practice, key user networks, physical co-location, temporary job rotations, or simply interdepartmental events. While IT reference frameworks largely neglect the less "formalizable" relational mechanisms, academic researchers have emphasized the importance of informal mechanisms as a necessary complement to formal mechanisms (Brown 1999; Chan 2002). For example, relational mechanisms are apt to facilitate knowledge sharing and mutual understanding among different stakeholder groups (Peterson et al. 2000).

57.2.4 Financial Autonomy

The strategic management and accounting literature differentiates between different forms of financial autonomy for divisional units, such as cost, break-even, profit, and investment center types (Anthony and Govindarajan 2007, p. 247). Applied to (corporate and divisional) IT units, the type of center not only has important implications for internal chargeback arrangements between business and IT but also determines the degree of financial and managerial autonomy of an IT unit (Venkatraman 1997).

Reference frameworks such as ITIL and COBIT generally acknowledge the importance of this organizational design dimension, but provide minimal design guidance.

In a *cost center* type, the IT unit is led by budget goals and is thus exclusively accounting for the costs of delivering internal IT services. Chargeback mechanisms are typically not in place (thus creating a possible incentive for business managers to underfund their units).

The *break-even center* defines service-based chargebacks based on the actual costs for delivering IT services. Thus, being a mixture between cost and profit centers, the goal of this center type is to close break-even. Since IT costs (e.g., for personnel, hardware, software) are often not directly accrued to an IT service, more complex cost and activity accounting schemes need to be established than in a cost center type. Such cost models often approximate the actually incurred IT cost, combining direct and indirect costs (Ryan and Raducha-Grace 2009).

Profit centers have greater financial autonomy inasmuch as their management carries responsibility for costs and (internal or external) revenues for IT services. Costs are charged to the customers on a more competitive basis, often oriented toward market-based transfer prices. However, in practice, business units are often obligated to contract with an internal IT profit center, so the degree of market competitiveness with external IT service providers is limited.

Investment centers extend profit center responsibilities to include accountability for the investment of accrued capital, so that this type of IT unit can be viewed as an independent company within the company. In large corporations, both profit and investment centers are commonly constituted in separate legal entities, subsidiary to the parent company.

57.2.5 Sourcing Arrangements

IT decision-makers continuously face the question about which tasks can be better and more efficiently performed by an external party. The IS literature provides a large body of literature with relevant considerations related to IT outsourcing (see Lacity et al. 2009 and Chapter 60 of this volume for an overview). Outsourcing arrangements can be differentiated regarding the coordination mode with an external provider—e.g., selected contractual obligations ("arms-length" relationships) for cost efficiency, versus long-term relational partnerships ("embedded") for strengthening IT resources and technological flexibility (Lee et al. 2004). Notably, in recent years, the focus has shifted from long-term, comprehensive IT outsourcing arrangements and purely economic considerations to contracts that also target quality, flexibility, and innovation goals (e.g., Whitley and Willcocks 2011). Recent literature also emphasizes the need for in-house capabilities for governing the different kinds of outsourcing relationships effectively (e.g., Willcocks and Griffiths 2010). One model of nine IS capabilities for modern IT organizations, for example, includes four capabilities that are directly related to managing outsourcing providers: informed buying, contract facilitation, monitoring, and vendor development (Feeny and Willcocks 1998).

While both ITIL and COBIT describe some processes and activities related to managing third-party services, from an enterprise design standpoint, the crucial concern is the *locus of outsourcing governance*, i.e., whether sourcing capabilities are allocated at the business level, the central, or the divisional IT side (Agarwal and Sambamurthy 2002). IT outsourcing decisions can also result in a change in decision rights for that particular IT function, including decentralizing more such rights to business units (Brown 2003). For example, in situations where resources for IT demand already reside in business units or divisional IT groups, this organizational configuration increases the outsourcing readiness of these units and thus the likelihood that an outsourcing relationship will be governed directly by the division. This may as well create more pressure on central IT units to compete with external providers—especially when business units are not obliged to contract internally. Financially autonomous IT supply units that are organized as subsidiary to their parent corporations (i.e., captive IT centers) can therefore also be viewed as transitional structural arrangements prior to outsourcing IT supply to an external party (Kreutter and Stadtmann 2009). In such situations, building appropriate demand-side IT capabilities may become a strategic priority (Feeny and Willcocks 1998).

57.2.6 Capabilities and Skills

We define a capability as *the application of knowledge, competencies, and skills residing in human resources, to accomplish given organizational goals* (Peppard and Ward 2004). Our second dimension, allocation of IT resources, refers to the structural assignment of human resources within the organization, whereas this dimension focuses on the aggregate proficiencies that IT human resources within an enterprise need to have. The IS literature has proposed different categories of capabilities in IT organizations. In addition to the nine-capability framework of Feeny and Willcocks (1998), a common typology derived from marketing research distinguishes between inside-out, outside-in, and spanning capabilities (Wade and Hulland 2004).*

Inside-out refers to capabilities that are internally focused, such as IT infrastructure, IT development, and (more generally) cost-effective IT operations—here referred to earlier as *IT supply* capabilities. Outside-in and spanning capabilities are externally oriented, placing an emphasis on requirements and customer relationships, including IT planning and change management, IT/business partnerships, market responsiveness, and external relationship management. These capabilities are likely to be aligned closely with business units and here we characterize them as *IT demand capabilities*.

Some more fine grained competency and skill categories can be found in both the academic and the practitioner literature, including a framework of 36 skills in 5 categories (Zwieg et al. 2006), skills related to roles in ITIL and CMM capabilities, as well as in frameworks such as the Skills Framework for the Information Age promoted by industry groups within the United Kingdom (SFIA 2012).† With the increasing pressure of IT organizations to compete on the product and labor markets, the development of appropriate IT demand and IT supply competencies becomes a more important imperative. A wide range of IT human resource practices, such as recruitment, training, and retention, and proactive career development can guide IT organizations to achieve this goal (Luftman 2011).

Table 57.1 summarizes the seminal literature that has motivated our inclusion of each of the six design dimensions.

57.3 IT Organization Archetypes

In Figure 57.1 we presented the four basic archetypes of IT organization configurations that are based on the first two dimensions described earlier: the distribution of IT decision rights and IT resources. In the following, we describe these archetypes in more detail, including their characteristics on the other four dimensions, their occurrence in practice, their strengths, as well as some common challenges.

57.3.1 Centralized Model

In a centralized model, most IT decision rights are allocated to the corporate level and IT resources are reporting to a central IT unit subordinate to corporate control while serving multiple business units. An IT steering or advisory committee has been recognized as an important coordination mechanism for ensuring business leader input into IT decision-making (Brown 2003; Huang et al. 2009). Under this model, the IT function is typically operated as a cost- or break-even center with simple chargeback arrangements. For example, in a corporate setting, a combination of global and business unit–related

* Although Wade and Hulland (2004) refer to these as categories for *resources*, their definition of resources as "assets and capabilities that are available and useful in detecting and responding to market opportunities or threats" is congruent with the notion of *capabilities* used in this paper.

† The SFIA Foundation is a not-for-profit organization that exists to own, promote, develop and maintain the Skills Framework for the Information Age. The members of The Foundation are UK Industry bodies in the field of IT: BCS (The British Computer Society), e-skills UK (e-skills UK Sector Skills Council Ltd), The IET (The Institution of Engineering and Technology), IMIS (The Institute for the Management of Information Systems), and itSMF (IT Service Management Forum).

TABLE 57.1 Design Dimensions and Primary Literature Sources

Dimension	Key Design Questions	Selected Literature
1. Allocation of decision rights	Which decision rights are allocated to business units, corporate, and IT stakeholders?	Brown and Magill (1994); Sambamurthy and Zmud (1999); Weill and Ross (2004); Brown and Grant (2005)
2. Allocation of resources	Which degree of centralization is appropriate? What is the split between IT demand and supply resources?	Boynton et al. (1992); Hitt and Brynjolfsson (1997); Thiadens (2005); Mark and Rau (2006); Daft (2009)
3. Coordination mechanisms	Which integration mechanisms (structural, procedural, relational) are implemented?	Brown (1999); Peterson et al. (2000); Chan (2002); Van Grembergen (2004)
4. Financial autonomy	Which degree of autonomy is appropriate for IT units? Which center type is implemented (cost, break-even, profit, investment center)?	Venkatraman (1997); Anthony and Govindarajan (2007); Ryan and Raducha-Grace (2009)
5. Sourcing arrangements	Which degree of external sourcing is appropriate? Which organizational units govern external relationships?	Agarwal and Sambamurthy (2002); Lee et al. (2004); Lacity et al. (2009); Willcocks and Griffiths (2010); Whitley and Willcocks (2011)
6. Capabilities and skills	Which capabilities are needed for IT demand and IT supply? How are these developed within the organization?	Feeny and Willcocks (1998); Peppard and Ward (2004); Wade and Hulland (2004); Zwieg et al. (2006); Luftman (2011)

IT budgets may be managed together with project-level and person-day based internal pricing. External contractors are typically governed by the corporate IT unit. Therefore, central IT resources not only need to be equipped with IT supply capabilities but also with sufficient IT demand capabilities to identify business needs and translate these into successful delivery by internal resources and external partners (as applicable).

Centralized models were the primary type of IT organization during the early era of mainframe computing and into the late 1980s when relational databases had arisen, however, networking was still limited (Peak and Azadmanesh 1997). A second wave of centralization also occurred in the mid-1990s as large firms initially implemented complex enterprise system packages (Brown 2003; McAdam and Galloway 2005). Today, centralized IT functions are also still the predominant model for small- and medium-sized businesses (Huang et al. 2009). Strengths of this model relate to an inherently high degree of standardization and corresponding efficiency through the sharing of IT resources and an underlying IT architecture across all divisions. Common challenges are business responsiveness and often a (perceived) lack of business contribution, that is, the IT organization may appear to act as a "black box" from a divisional perspective. Many centralized models have experienced improvements in IT responsiveness by enhancing both formal and informal coordination mechanisms, e.g., by introducing dedicated liaison roles and cross-functional IT meetings (Brown 1999; Huang et al. 2009).

57.3.2 Decentralized Model

In a decentralized model, business units make IT decisions (divisional or lower level) and are also responsible for managing IT resources. In the pure decentralized model, a central IT unit does not exist, which means that today it can be viewed as an almost "anarchic" configuration, with no or little coordination on a corporate level (Weill and Ross 2004, p. 58). In small divisions, coordination can even be achieved via informal, relational mechanisms; costs may not be accrued as a separate IT budget; and chargeback arrangements may not be implemented. If decentralized models make use of external suppliers/contractors, potentially for selected IT sourcing or project resources, these are typically governed outside of corporate control.

The decentralized model became more common after the expansion of mini-computers in the late 1970s, when most of the information processing took place in closed (proprietary) systems managed

by local IT experts (Peak and Azadmanesh 1997). The rapid growth of desktop computing and more modern distributed computing architectures also facilitated more decentralization (Von Simson 1990). The disadvantages of this model as a "pure" model lie in the cultivation of silo structures and a lack of IT cost transparency. Similar downsides relate to the commonly undesirable phenomenon of "shadow IT," i.e., the existence of ad hoc IT solutions built, used, and managed by the business without central involvement or approval (Raden 2005). However, decentralized configurations can still be appropriate in cases where a strategic independence of a certain business division is desired, which may even include divestment-readiness (Leimeister et al. 2012). This model can also be appropriate for business functions where high innovation through IT and autonomous IT use are a strategic imperative, for example, in the research and development departments in a technology-intensive industry.

57.3.3 Shared Services Model

In the shared services model depicted in Figure 57.1, the IT resources are highly centralized, while the IT decision rights are primarily located at the division level. That is, divisions share the usage of centralized resources to capture advantages associated with a centralized model—including economies of scale and scope and IT architecture planning—without giving up major decision rights to a corporate IT unit. The business divisions typically also participate in steering committees and other decision-making bodies—such as cross-divisional IT boards responsible for IT architecture, IT application prioritizations, and infrastructure management—to set priorities for all of the divisions using the centralized IT resources. Shared services units are financially more autonomous than a purely centralized model and are responsible for their own results (Schulz et al. 2009). IT organizations that transition to this model therefore often need to devote significant efforts to productize their IT services on a competitive cost basis, so that they can retrieve their costs with chargebacks to their business customers (Ryan and Raducha-Grace 2009). External service providers may also be contracted for, and governed by, the shared services unit, especially for infrastructure services. However, depending on their size and maturity—and policies of the overall organization—business divisions may also have sufficient IT demand capabilities (and authorization) to independently contract out to external parties and thus circumvent the shared services unit.

Some of the early roots for this model can be seen in the writings by Von Simson (1990) and others in the 1990s, when organizations sought to better balance the advantages of a centralized model with those of a decentralized model with hybrid approaches. One hybrid approach was to create a federal model with IT application rights *and* resources residing within the divisions or business units, but IT operations (rights and resources) in a corporate IT unit. In contrast, in a "pure" shared services model, IT decision rights are at the division level, but IT (both application and infrastructure operations) resources are centralized. The global implementation of enterprise systems beginning in the late 1990s, which required both centralized application maintenance and process-based customizations, has been one of the catalysts for a wider acceptance of the pure shared services model (Brown 2003).

In many corporations today, shared services have therefore become a dominant model to organize and deliver IT as well as other enterprise support functions (e.g., accounting, physical facilities management), which are therefore sometimes co-located with IT (Schulz et al. 2009). Companies thereby aim to combine the benefits of centralization (economies of scale and scope) for IT applications and operations, with the benefits of outsourcing (e.g., customer focus, quality orientation, and increased variable versus fixed costs at the division level)—without sharing the potential drawbacks of outsourcing to an external supplier (e.g., supplier sustainability, loss of internal know-how, regulatory compliance, and data security concerns, etc.).

Sometimes this model is also seen as an opportunity to generate additional business, or as a strategic step before entirely outsourcing IT operations. Until the mid 2000s, many major corporations set up such IT subsidiaries with the primary goal of generating external revenues during a time of tremendous IT expansion in developed countries—a strategic trend that from today's perspective, with few

exceptions, can be counted as a failure (Kreutter and Stadtmann 2009). Reasons for why many of these "captive" players could not sustainably hold ground in an external market include the changing capability requirements for internally versus externally competing service providers, and the rise of mature IT outsourcing firms that utilize cheaper labor.

Some of the inherent challenges of this model also relate to the lengthier channels of communication from business demand to IT supply units (delivery), which may need to be coordinated across multiple division (and country) boundaries. For this reason, sophisticated governance mechanisms, including service level agreements by business units, as well as strong demand-side IT capabilities, are required in order to implement this model successfully (Peterson et al. 2000; Van Grembergen 2004).

57.3.4 Corporate Coordinator Model

In the corporate coordinator model, IT-related tasks are performed externally or by divisional resources (i.e., by divisional IT units or non-IT business users themselves), while a central IT authority (office of the CIO, or in some cases a CTO*) governs through IT decision rights and aligns the IT resource investments with an overall IT architecture strategy. In the "pure" form, the office of the CIO is empowered to develop and enforce standards and monitor adherence via the CIO's direct report to corporate management, but does not possess dedicated resources to provide IT supply. Corporate IT standards differ in extent and range, from the usage of certain technology platform and application standards to guidelines for risk management and security controls. The reliance on committees and other coordination mechanisms to balance corporate and cross-functional priorities is similar to the shared services model. However, in a corporate coordinator model, these governance bodies are under the CIO, who has greater decision-making rights. For example, large IT development projects and sourcing arrangements to be managed at the division level may require pre-approval from the CIO.

External providers are contracted centrally by the office of the CIO or by divisional IT groups, depending if the service being sourced has firm-wide impacts (e.g., infrastructures and communication) or only divisional impacts (e.g., consultants and IT specialists in a project context). The CIO office acts as the mediator of external IT services, which are charged back to the divisions based on the costs of provision. Financial autonomy of the internal, divisional IT units is generally low, costs are accrued to divisional IT cost centers that are consolidated in divisional budgets, and no chargebacks take place at the division level. However, global cost transparency is warranted through oversight by the CIO and a global portfolio of divisional and corporate IT projects. For IT supplier steering and internal as well as external coordination, the central CIO office needs to develop strong demand capabilities (e.g., IT planning and change management, market responsiveness, and external relationship management). IT supply typically takes place through external suppliers or through divisional IT resources (as applicable).

The corporate coordinator model in its pure form is appropriate for several particular contexts, of which we highlight three. First, establishing a CIO office is often used strategically as a first step to advance from very decentralized configurations to more centralized governance and transparency, before actually centralizing resources, consolidating infrastructures, and achieving global scale. Second, for some business models that are based on replication (i.e., different entities with low data integration needs, but similar business processes), a coordinator model is the appropriate choice, due to its ability to leverage standardization potentials and economies of scale in IT sourcing, without integrating IT architectures (Ross et al. 2006, p. 35). Examples for such business models are diversified conglomerates as well as franchise companies.

Finally, the CIO office as a mediator of external IT services enables the ongoing IT outsourcing and industrialization trend. That is, the more (diverse) services are procured from the external market, the

* The Chief Technology Officer (CTO) role has evolved from research and development (R&D) management positions in technology-based industries and has recently also attracted more attention as a point of strategic responsibility for long-term goals and guidelines for the use of information technology within organizations (Hunter 2011).

TABLE 57.2 Key Characteristics of Four IT Organization Archetypes

	Centralized	Decentralized	Shared Services	Corporate Coordinator
IT decision rights allocation	CIO with senior management support	Business unit leaders (separately)	Business unit leaders (federally) and central CIO	Central CIO office enforcing standards, local implementation
IT resource allocation	IT resources in corporate IT	IT resources in local divisions	IT resources in shared IT unit, few IT demand resources	IT resources in divisions or external, few strategic IT resources in CIO office
Coordination mechanisms (structural)	Business relationship managers, IT steering committee	Divisional IT heads, divisional management boards	Divisional IT managers, central account managers, cross-divisional IT boards, e.g., IT architecture board	Executive board, divisional IT heads, architecture board
Financial autonomy	Cost or break-even center, simple chargebacks	Cost center or accrued to other budgets, no chargebacks (for small divisions)	Break-even, profit or investment center, productized chargebacks	Chargebacks for external IT services, cost centers for divisional IT, global monitoring
Sourcing arrangements	ESPs[a] governed by corporate IT	ESPs[a] governed by divisional IT	ESPs[a] governed by corporate IT or divisional IT	Firm-wide ESP[a] contracts governed by CIO office, specialist ESPs by divisional IT
Capabilities and skills	Good demand capabilities in corporate IT needed	Demand from business, supply capabilities in division IT	Ideal split of IT demand and IT supply capabilities realized	Demand capabilities in CIO office, supply capabilities in division IT (or externally)
Strengths	Standardization, resource pooling, efficiency	High responsiveness and local innovation, strategic independence	Economies of scale and responsiveness, customer-orientation, IT cost transparency	Expert sourcing by CIO office, standardization, global IT cost transparency, strategic independence
Common challenges	Lack of business value contribution, low flexibility	Lack of efficiency, low cost transparency, silo structures	More complex governance and communication structures, IT supply competes externally	Difficult to empower CIO office, lack of strategic IT competence in business divisions

[a] ESP, external service provider.

higher is the need for expert buyers to steer and manage these providers in order to achieve the desired benefits (e.g., costs, flexibility, and innovation goals). Thus, establishing a corporate coordinator model can be a viable alternative to building the distributed and costly demand capabilities in the business divisions—as required for the shared services model.

The key challenge of the corporate coordinator model is its difficulty in effectively implementing centralized IT governance to leverage economies of scale and standardization via negotiations across division heads. This may explain why this archetype—as a model for the entire IT organization—is still uncommon today in practice.

The four IT organization archetypes and their key characteristics are summarized in Table 57.2.

57.4 Assessing the Business and Technology Contingencies

Past research has proposed traditional business drivers such as a firm's competitive strategy and structure as influencing the "choice" of the archetype of an IT organization (Agarwal and Sambamurthy 2002; Brown and Grant 2005). For example, more globalized firms seeking responsiveness to local markets are likely to decentralize some IT rights and responsibilities, while smaller firms striving for economies of

scale are likely to centralize their IT decision rights and resources (Sambamurthy and Zmud 1999; Weill and Ross 2004; Huang et al. 2009). However, more recent literature also emphasizes the complementarities between organizational and technological architectures (Tiwana and Konsynski 2010).

We conjecture that recent technology trends such as cloud computing and IT consumerization are likely to affect the IT organization models for both the IT demand and the supply sides. More specifically, cloud computing and the Internet-based delivery of applications and components as a service will further push the border of what is "core" and what is "commodity" across enterprise application landscapes (Bento and Bento 2011). Thus, on the application level, business units are more likely to manage their own cloud applications in a more decentralized fashion and thus circumvent centralized investment procedures (Winkler et al. 2011). At the backend, fewer IT resources will be needed for the operating infrastructure. However, managing the technological architecture and integrating cloud-based services with internal and external infrastructures will pose increasingly important challenges and the need for new capabilities.

Consumerization of IT superimposes the cloud wave. Employees with increasing IT skills and access to sophisticated client devices for personal use expect to find IT tools in their workplace that they already use in their home environments (Bernnat et al. 2010). As an answer to these new expectations, some companies have created policies for allowing employees to bring their own devices, such as smartphones and tablet PCs, into the work environment and integrate them. This represents a paradigm shift inasmuch as employees are subsidized for using their own hardware and applications. Data security and other related risks need to be diligently addressed by enforcing appropriate firm-wide guidelines.

These and other technology trends suggest greater decentralization of IT responsibilities and more hybrid IT governance designs in the future. More application as well as infrastructure decision rights (e.g., on mobile device use) will shift to tech savvy business users, while IT operations responsibilities are increasingly shared between internal and external suppliers. Managing the diverging ecosystem of user IT demand and entire supply chains of IT service provision will be one of the key IT governance challenges in the future (McDonald 2007). Enterprise-level organizational models that enable a better integration and coordination across users, IT units, and multiple suppliers will need to be developed, which we expect to be reflected in future versions of standard IT reference models (Pardo 2010; Marrone and Kolbe 2011).*

57.5 Further Research Opportunities

Beyond the technology contingencies, other perspectives also appear particularly fruitful for investigating the changing shape of contemporary IT organizational configurations. First, industry-specific approaches have largely been neglected in the past. Organizations in the public sector, for example, national and local governments as well as non-profits in health care and other industries, hold different principles for creating public versus private value, which may also call for different principles of IT governance (Weill and Ross 2004, pp. 185–214; Sethibe et al. 2007). Second, given the increasing dispersion of IT value creation across organizational ecosystems, the understanding of "organizational configurations" needs to be broadened to span entire IT value networks (Leimeister et al. 2010; Iyer and Henderson 2012). This also implies that the extensive, yet separate, literature strands on governance of (internal) IT functions and governance of (external) outsourcing relationships need to be united under a common frame. Third, such governance arrangements may significantly vary depending on the kind of IT subfunctions considered. Various authors have begun to investigate IT organization and governance phenomena regarding certain subdomains, such as governance in system development projects (Tiwana 2009), application governance (Winkler et al. 2011), data governance (Khatri and Brown 2010), and infrastructure sourcing governance (Xue et al. 2011). Taking such modular views and aligning these with overall (networked) governance schemes appear a promising

* For example, in its 2011 version ITIL has introduced additional strategic processes and liaison roles to address increasing coordination needs, such as a service strategy manager, a business relationship manager, and a demand manager.

field for future researchers. Finally, having argued that organizational configuration is a dynamic phenomenon influenced by business and technology developments, we conclude that more longitudinal research is needed to study IT organization design phenomena.

In this chapter we conjecture that implementing more characteristics of a corporate coordinator model—i.e., moving operational IT delivery to external specialists while focusing on the alignment of internal standards and decentralized provisioning of specialist resources—may become a viable path for many CIOs to address the design issues related to the IT organization dimensions discussed here. This also implies that the CIO role will continue to evolve from an "inside-out" IT supply manager to an empowered coordinator, who leverages capabilities of the entire IT value network from the outside-in—a role that has also been termed as a *chief business technology strategist* (Carter et al. 2011). Future researchers may build on our enterprise-level view of four archetypes of IT organizations and their dimensions, as well as assess in-depth the impact of emerging IT trends on IT organizations in different, dynamic business and industry contexts.

Topics of Conversation: The New Agenda for the CIO

Joe Peppard
European School of Management and Technology

Today, most organizations are so fundamentally dependent on their information systems and technology that they could not operate for very long if their core systems were not available. Organizations such as Tesco, Fed Ex, ING Bank Direct, and Commonwealth Bank of Australia derive competitive advantage from their IT investments while others, such as Amazon, Lastminute, threadless, and eBay, have business models that are totally defined by IT. Many organizations are currently looking at ways to potentially harness technologies such as "the cloud," Web 2.0, social media, and collaborative tools. We also see traditional manufactures like Rolls Royce, MAN Trucks, BAE Systems, and Hilti using IT to enable the delivery of new service propositions to their customers based around availability and capability rather than selling products. Yet despite this crucial role of IT for business today and the opportunities that it provides, research findings are unequivocal: leadership of IT in most organizations is generally weak.*

Many of the CEOs that we speak to continue to lament that they are disappointed with their IT investments and the contribution they feel IT is making to the operational and strategic development of their businesses. They are unanimous in expecting more of their CIOs than merely "keeping the

* See, for example, *Leadership, Capability and Culture: The CIO's Silent Revolution*, IBM Corporation, London, 2009; *Strategic Insight Survey: A US IT Leadership Perspective*, Harvey Nash, 2009; *The CIO Profession: Leaders of Change, Drivers of Innovation*, Center for CIO Leadership, 2008; *The CIO Profession: Driving Innovation and Competitive Advantage*, Center for CIO Leadership, October 2007; *The Evolving Role of the CIO*, IBM Global Services, 2008; *The New CIO: Change Partner and Business Leader*, IBM Corporation, 2007; *Global CIO Survey 2007: IT Agility—Enabling Business Freedom*, Cap Gemini, 2007; *Global CIO Survey: The Role of the IT function in Business Innovation*, Cap Gemini, 2008; *CIO 2.0: The Changing Role of the Chief Information Officer*, Deloitte, 2004; *Circa 2015: The CIO of the Future*, Software AG, 2008; *Information Technology II: How To Close the CIO Leadership Credibility Gap*, Accenture, September 2006.

lights on." Increasingly, many are now demanding their CIO to drive the transformation agenda and are looking for IT to seek out opportunities for integration and innovation. However, our research indicates that a considerable number of CIOs are struggling with this new expectation. Whether a consequence or a contributor, many CIOs are reporting to us that strategic conversations are taking place within their organizations without their involvement.

What we have found is that a lot of the CIOs that we have spoken to say they are strategic, but in reality they behave tactically [1]. From our interviews with their business colleagues, many CIOs would seem to lack credibility as strategic decision-makers and consequently are not invited to be part of the "inner sanctum." Even where they do have a "seat" at the top table, they often do not have a "voice," particularly one that is readily listened to. Furthermore, we also observe that many CIOs lack basic influencing skills [2] and have not developed relationships with appropriate parts of the organization or key stakeholders [3].* Consequently, they are seen by their business colleagues as being politically naive [4]. And, perhaps more crucially, many lack the leadership capabilities to drive their organizations forward in the use of technology.

This situation is inhibiting CIOs not only in the performance of their role but more critically hindering the business in optimizing value from information systems and technology investments. In our research, we have talked to dozens of CEOs, CIOs, and other C-level executives in order to better understand why it is that some CIOs do seem to be having significant impact on the performance of their organizations and others are not (see Appendix for overview of this research).

The attitude that the CEO and executive team have toward IT does have an obvious impact on what the CIO can and cannot do. Many portray IT "*as a pain*," see "*everybody moaning about it*," and adopt a "*don't bother me attitude*" toward IT. The fact is the level of IT savvy of many CxOs is weak [1,5]. This situation strongly influences their expectations of what CIOs can and cannot be expected to achieve, the extent of their engagement with the incumbent, their contribution to IT decision-making, and their involvement in IT projects and programs. It also shapes their view on the opportunities that technology could potentially provide their organization. Yet, research findings are emphatic that companies reporting a higher level of business-IT alignment have a shared vision between the CIO and CxO team and a common set of core beliefs regarding IT [6].

We have also detected a gap between the rhetoric of CxOs and their actions. That is, they typically say that they recognize the crucial importance of IT, yet they behave in ways that do not back up this position. One newly appointed CIO had a conversation with one of the members of the senior leadership team (he reported into the Chief Financial Officer) in which he congratulated the CIO on his work since joining the company *"as we [the leadership team] have not had to talk about IT since you came on board!"*.

While all CIOs grapple with similar issues, what we have found is that some are more adept at meeting many of the contemporary challenges that they all face. These individuals have become extremely effective in helping their organizations deliver maximum value from their IT investments. These are what we have called *Hi-Impact CIOs*.

Hi-Impact CIOs are those CIOs who are seen by their business colleagues as driving the business forward through the use of IT. These CIOs typically have the trust of their business colleagues; they are seen as a respective member of the executive team; and continuously interact with their business colleagues. Perhaps not unexpectedly, they are also seen as listening to their business colleagues, being empathic to their plight and demonstrating a passion for enabling the business with IT. Their credibility is such is that it enables them to influence business colleagues in IT matters. Not only do they have a seat at the top table, they also have a voice that is listened to.

From our data, there is strong evidence that Hi-Impact CIOs have retooled not just how they interact and communicate with their business colleagues but also have shifted the nature of that interaction. In short, there is strong evidence that they have reframed the dialogue that they have with CxO colleagues. They report that it is not just about having conversation with their colleagues, but having the

* See J. Peppard and J. Thorp, 'What every CEO needs to know and do about IT', manuscript currently under review

right conversations. Research shows that high levels of communication between IT and business executives are a direct predictor of alignment of business and IT strategies [7]. And CxOs rank communication as the personal skill most pivotal to success as a CIO.*

To provide context for the research presented in this chapter, we first briefly review the evolution of the CIO role in organizations. This evolution reflects the changing role for IT in organizations and the strategic implications that it now has. This analysis also highlights the ambiguous nature of the role. We then present the changing topics of conversations that Hi-Impact CIOs are having with their C-level colleagues.

58.1 Evolution of the CIO Role†

The genesis of the CIO role and indeed the coining of the "chief information officer" label can be traced to a shift from IT having a supporting role in organizations, automating previously manual tasks, to being a driver of competitive advantage, strategic change, and innovation. This latter objective demands considerably more than just a focus on technology deployment and its management—which the CIO's predecessors did—requiring business-driven approaches for the exploitation of information and IT. Increasingly, information was recognized as a critical resource that required active management, stewardship, and oversight from a senior management perspective [8].‡ The newly created position of CIO [9]§ emphasized information over technology, enterprise over function, and strategy over operations. Indeed, it was not that incumbents were no longer responsible for technology, the role just expanded. In addition to the operational dimensions, the position had a key requirement to provoke executive level discussions across the organization relating to how information and technology could be leveraged, particularly in the pursuit of competitive advantage.

It was in this quest for executive engagement that organizations began to make the distinction between *demand* and *supply* [10]. "Demand management" was concerned with identifying the information required to both shape and deliver the business strategy as well as prioritizing IT spend. This was promoted as a business-led activity. The supply side was concerned with satisfying these requirements through the sourcing and deployment of IT [10,12].¶ While demand would be determined by business executives working closely with their CIOs, or achieved by establishing a demand organization containing relationship and "hybrid" managers [11], efficient and effective supply was the responsibility of the CIO.

Despite this opportunity for CIOs to increase their impact in the C-suite, many have struggled. While clearly some may not be up to the job, this can be seen as a consequence of the polarization of views held by CxOs regarding the role of technology in organizations [13]: at one end is the belief that IT is an administrative expense and a cost to be minimized, while at the other is the stance that it offers significant strategic opportunities. This fundamental dichotomy perhaps manifests itself in

* State of the CIO Survey 2007', *CIO*, January 2007.

† This section draws heavily from my paper with colleagues "Clarifying the ambiguous role of the CIO," *MIS Quarterly Executive*, Vol. 10, No. 1, 2011, pp. 31–44.

‡ Applegate and Elam [8(a)] suggest that the rise of the CIO marked the transition from the DP era to the information era.

§ Credit for coining the label "Chief Information Officer" is generally attributed to William Synott at the 1980 Information Management Exposition and Conference. Synott predicted that "The manager of information systems in the 1980s has to be Superhuman—retaining his technology cape, but doffing the technical suit for a business suit and becoming one of the chief executives of the firm. The job of chief information officer (CIO)—equal in rank to chief executive and chief financial officers—does not exist today, but the CIO will identify, collect and manage information as a resource, set corporate information policy and affect all office and distributed systems." *Business Week* ran a story in 1986 announcing the arrival of the CIO.

¶ The concept of "the hybrid manager" was also promoted at this time. First coined by Peter Keen in 1988, it was defined by Michael Earl as "people with strong technical skills and adequate business knowledge, or vice versa … hybrids are people with technical skills able to work in user areas doing a line or functional job, but adept at developing and supplementing IT application ideas."

the different perceptions of the role of the CIO, job tasks, reporting relationships and what a CIO can be expected to achieve. It also determines the level of engagement and involvement of CxOs in what might traditionally have been considered as IT issues and decisions. One study has highlighted the "IT decisions the IT people shouldn't make." [14] But even in situations where CxOs subscribe to a more strategic view for IT, they often do not understand what *their* role and the wide responsibilities of "the business" in optimizing value from IT spend. This has been attributed to weak levels of digital literacy [1].

An examination of the prior research regarding the CIO role identifies a number of distinct themes. The early research explored the nature of the CIO position, in particular the mix of business and technical knowledge required of incumbents. Key prescriptions were that the CIO must operate as a corporate focused executive rather than a functional manager and that success in the role required bringing a broad business perspective to the position [8a]. Early research also revealed that those who thrive as CIOs recognize the importance of executive relationships particularly with the CEO [3].

Most of the contemporary research falls into two streams: either advocating that CIOs take a stronger and more proactive leadership role in their organization or exploring the personal competencies of successful CIOs. The former stream of research promotes the need for CIOs to lead change (sometimes using the word "transformation") and drive innovation. It recommends that they must expand their remit beyond merely "keeping the lights on" to having a more strategic role. As some recent papers have expressed: "to find ways for IT to change the company, not just run it," [15] and "take a much broader role in the business, driving business transformation, innovating for competitive advantage and acting as key strategic partners to the CEO and wider organization." [16] Studies in the latter stream explore the competencies, personal attributes, and characteristics that are seemingly required for success. Leadership, influencing, relationship architect, diplomat, etc. are promoted as crucial competencies [2a,17]. Personal attributes identified for success in the role includes communication skills, business acumen, people skills, openness, and conscientiousness [18].* As with the prescriptions from earlier studies, the CIO is envisioned to be more a business expert than a technical expert. Research in this genre has also reported on CIO leadership profiles (mapping "CIO authority" against "leadership capability"), although the construct of CIO leadership capability has not been well developed [19].

While interesting, much of this latter research has tended to add little to help organization as they seek to capitalize on IT. For example, prior research seeks to discover the different competencies (although the term "roles" is used in some studies) of CIOs. Competencies identified include: strategist, relationship architect, integrator, information steward, and (IT) educator. While useful, they are not grounded in a precise understanding of the *job* of the CIO and what incumbents are expected to achieve for their organization. In addition, the assumption of these studies is that if incumbents possess these competencies, they will be successful as CIOs. However, are these competencies not generic and required by all in the C-suite? Should not all members of the C-suite be business leaders, strategic thinkers, driving change and innovation? We would strongly argue that they should.

58.2 Shifting Conversations of the Hi-Impact CIO

What we have found is that Hi-impact CIOs have moved the focus of their attention away from the traditional areas of conversation: Hi-impact CIOs place their emphasis elsewhere. What we see are subtle, but nonetheless profound, shifts away from what have traditionally been seen as areas of focus for CIOs. Our research has identified eight shifts that together contribute to these CIOs having a major business impact (see Appendix for an overview of this research).

* Research has reported, for example, that CIO characteristics can explain a large proportion of variance in organizational innovative usage of IT see [18].

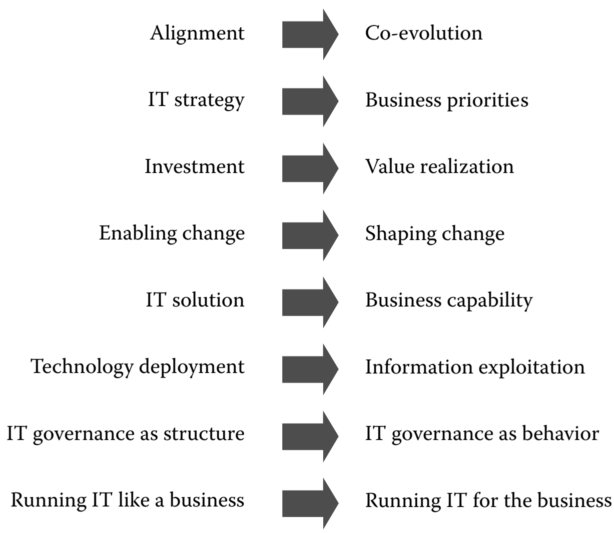

FIGURE 58.1 Shifts in CIO:CxO conversations: the new agenda for the CIO.

These shifts are captured in Figure 58.1. The left hand column lists the traditional areas of CIO attention, illustrating where the focus of their conversations have tended to lie. On the right are the corresponding areas of emphasis placed by Hi-Impact CIOs. These swings point to a new agenda for the CIO. In the remainder of this paper we will have a closer look at these shifts, identifying how each is manifesting itself.

58.2.1 From Alignment to Co-Evolution

For over three decades alignment has been the watchword of the CIO. Indeed, surveys of IT issues over the past 30 years have consistently ranked the challenge of achieving alignment among the top three [20]. CIOs themselves have always seen as one of their primary tasks to aligning their organization's portfolio of investments in information technology (IT) with the strategy of the business. While this is a laudable objective, it, of course, assumes that organizations do actually have an explicit business strategy which can be aligned against. Many CIOs have told us that this unfortunately is often not the case; and, even if a business strategy exists, it might not be shared across the executive management team.

Hi-impact CIOs, however, do not see the issue as one of alignment but one of co-evolution: that is, business and IT strategies co-evolving together [21]. Importantly, and this is the critical issue, the focus on alignment gives the impression that it is a task that is undertaken by the CIO and his team, and that IT requirements are somehow subservient to the demands of the business. One CIO spoke about seeking alignment equal to looking to align the human "heart" with the "body," which he saw as an illogical demand. Both are mutually dependent. As one CIO expressed it: "*just like we don't have IT projects any more, only business projects with an IT component, similarly, we don't have an IT strategy but a business strategy with an IT component.*"

In a similar way with biological organisms [22,23]*, with co-evolution both business and IT co-evolve together. An Australian CIO defined co-evolution as a "psychological state" with "business and

* The term "co-evolution" was coined in the 1960s by the American population biologist Paul Ralph Ehrlich and the botanist Peter Hamilton Raven to refer to evolutionary changes that occur in genetically unrelated species as they interact with each other in their environment.

IT working as one toward a common goal." This, however, demands high levels of trust, cognitive alignment, a shared understanding across all parties and strong collaboration [6a], something that is all too often absent.

Co-evolution recognizes that IT can also shape the strategy of the organization through providing innovative opportunities, particularly with new business models defined by IT. For example, many traditional manufacturing companies are today implementing service-based strategies and these new business models are heavily dependent on IT. For example, in the aerospace sector, engine manufacturers such as Rolls-Royce, General Electric, and Pratt & Whitney all offer some form of performance-based contracts with commercial airlines in which their compensation is tied to product availability and the capability it delivers (e.g., hours flown) rather than selling engines. Such contracts provide the airline operator with fixed engine maintenance costs over an extended period of time (e.g., 10 years). Yet to deliver such a service both effectively and profitably demands IT: data on engine performance must be collected in real-time, transmitted, and analyzed by the engine manufacturer at a health monitoring centre using prognostic and modeling tools.

58.2.2 From IT Strategy to Business Priorities

A key prescription for the CIO has always been to develop the organization's IT strategy. Indeed, this task usually appears in their job specification and is an expectation that their C-level colleagues hold of them. The reality is that many struggle to engage their business colleagues in the IT strategy formulation process and often end up "second guessing" the strategy and future business direction, particularly when one is absent. Our data indicate that Hi-Impact CIOs are shifting their dialogue with C-level colleagues from one focused around developing this IT strategy to having a conversation based on eliciting their business needs and priorities. These CIOs tell us that this approach is more likely to get the attention of their colleagues. One CIO we spoke to prefers to engage with his peers about their "initiatives," and to use these to validate their priorities and construct the IT investment portfolio. He determines what their initiatives are for the following 6 months, the next year, and the next 3 years, and then presents these back to them in a coherent fashion and one that makes sense to them before highlighting how IT can support their achievement. This, he also felt, enhanced his relationship and reputation with the leadership team as they see him as listening to them.

Such is the peril of focusing on the IT strategy that the recently retired Global CIO of a global pharmaceutical company warns that CIOs should "beware the IT strategy," as it can become an end in itself. This does not to suggest that a strategy for IT is not required; on the contrary, one is required now more than ever. However, developing this strategy should not be seen as a central focus of interactions with business colleagues. Focusing on the business priorities of colleagues is more likely to gain their interest and attention. From this dialogue, the basis of an IT strategy can be ascertained. It also gives guidance as to the priorities for IT investment as well as setting expectations for IT. The Head of Technology at one U.K. retailer commented that "*[t]here's no point in us wondering later why IT hasn't delivered what was expected if there hasn't been a clear upfront conversation between IT and the rest of the business about business priorities for the next 5/10 years; in particular what the problems are that the business will need IT to help solve*."

Indeed, CIOs often lament the lack of an explicit business strategy and this absence is often used by CIOs to excuse poor performance. One Non-Executive Director of an Australian insurance company recounted to us the visit he had from a newly appointed CIO complaining about the lack of a business strategy and how this was impacting her in her job and her frustration with this situation. This is, unfortunately, the platform from which many CIOs are working from. Her colleagues do have their priorities and it is hard to imagine an insurance company without IT having a significant impact.

We have also encountered situations where prescribed practices can often dictate that a separate IT strategy be developed. The legislation of the State of Queensland in Australia, for example, mandates that an annual IT strategy plan be developed for all public agencies, one that is aligned to the strategy of the agency. It even prescribes the process to ensure that this occurs, with the IT strategy

trickling down from the business strategy. This can be problematic and reinforces the old orthodoxy of the IT strategy following the business strategy.

58.2.3 From Investment to Value Realization

Hi-Impact CIOs are telling us that conversations with C-level executives must shift from one centered on determining investments to a dialogue focused on value realization. They explain that value realization has a more dynamic and ongoing connotation than merely determining investments in IT. One CIO wryly lamented the fact that IT investments tend to be characterized based on their cost—"the 50 m dollar ERP project"—rather than described based on the value they will deliver to the business.

This might seem like a subtle shift in emphasis, but its implications are profound. A focus on identifying the investments to make suggests that the decision to spend is made by business executives with delivery managed by the CIO and his/her organization. Unfortunately, unlike other investments that a firm makes, the value of IT is not in its possession. If it was, just building and deploying IT-based systems successfully would result in benefits automatically flowing to the business, and we know that this is not the case. Few IT projects fail because the technology does not work. The reality is that generating value through IT is an organization wide endeavor with executives and employees having a role to play.

Organizations do not buy IT *per se*; what they do buy is value, or at least potential value. Unlike physical assets, IT has no inherent value and the possession of IT itself does not confer any value. This value has to be unlocked. This value emerges through change that the technology both enables and shapes: process change, new work practices, and improved decision-making [24]. Our research suggests that more business managers are getting involved in building business cases for IT investment; but once the approval for the spend has been received, it is then passed on to "IT" for delivery. They tell us that they feel comfortable in so doing as IT organizations tend to be driven by methodologies. Yet, they fail to recognize that such methodologies focus on technology deployment and not on generating value. By emphasizing the process of value realization, the focus is not just on getting approval for the spend, but on managing the life cycle of the investment and the process of value realization. Hi-Impact CIOs also suggest that to promote this behavior the business case must become a living document and accompany the investment through its lifecycle [25].

58.2.4 From Enabler of Change to Shaping Change

To have business relevance, Hi-Impact CIOs look to shape change in their organization, rather than merely responding to business requests. This is in recognition of the power and capability of IT to enable the organization to do things differently, both operationally and strategically. Some CIOs have even taken up leadership of the transformation agenda in their organizations. These CIOs acknowledge the power of innovation though IT and relish the challenge of seeking such opportunities out. However, to do this requires credibility [26]. Hi-Impact CIO tells us that this has nothing to do with one's CV; it is all about the relationship with CxO colleagues.

Hi-Impact CIOs shape change through innovation, seeking opportunities to marry emerging technical capability with business opportunity. They have typically dedicated budget and resources for innovation, constantly searching out new technologies and assessing their business relevance. They also work in close partnership with business colleagues to stimulate discussions and generate ideas for potential IT application.

We have also seen Hi-Impact CIOs recognizing the tension between "business pull" and "IT push." On one hand, they readily acknowledge the challenges of IT push, but their credibility gives them a strong voice. They realize that most "game-changer" innovations come from technology that their business colleagues can be slow to spot. But by having the trust of their business colleagues and credibility, they have the opportunity to "advocate" the idea to them. Of course, as a member of the leadership team, they also seek to "pull" ideas and opportunities from their business colleagues as well as working with the wider ecosystem of customer, suppliers, and business partners.

58.2.5 From IT Solution to Business Capability

In the past, the IT industry was criticized for selling the features and functions of products. In response, CIOs have generally emphasized the provision of solutions to the "problems" of business colleagues. However, what Hi-Impact CIOs are telling us is that the concept of the solution can typically result in business managers abdicating responsibility to the IT organization to provide *the* solution to *their* problems. Too often we hear the comment "*SAP will solve our problems*." Even today, project management methodologies like PRINCE 2* are designed around building "the product"—the product being a combination of hardware and software. Hi-Impact CIOs prefer to emphasize the capabilities they are providing the business. The implication is that the business has to leverage these capabilities if the expected benefits of the investment are to be achieved.

What CIOs are telling us is that in promoting IT solutions, the focus is on "the IT" not "the problem" that requires solving. Consequently, IT is seen as a solver of problems: this is the magic bullet thesis. They report that it can also cause CxOs and other executives to disengage once the program for execution has been developed as addressing the problem is seen as an IT endeavor. Building the IT capability is just one element of larger program of work. Focusing on providing a business capability is more likely to get the attraction of business managers as it emphasizes business and IT working together to create a capability for the business to exploit.

58.2.6 From Technology Deployment to Information Exploitation

Hi-Impact CIOs recognize that while successfully implementing technology is necessary, on its own it is not a sufficient condition to generate value. Ultimately, value emerges from the usage of information and IT [27]. Yet, if we examine how organizations run a typical IT project, we observe a strong emphasis on the deployment of technology. Project metrics such as on-time delivery, within budget, and meeting the specification are reinforcing this emphasis [28]. While benefits from technology can be achieved through automation of organization processes, taking out time and cost, and other inefficiencies, the real value is through working with information. This is a neglected aspect of IT investment. It is more than just training, but a conversation around how the new information will be capitalized on.

One CIO expressed this as a shift from "delivering IT" to "delivering business value," but also acknowledged that it demands a shift in mindset that should not be underestimated. Not cultivating the ability to work with information is one of the key reasons why many IT projects fail to deliver expected business benefits. Research on CRM, for example, has found that organizations which did not develop competencies among users to work with information did not see much in return for their investment [29].

58.2.7 From IT Governance as Structure to IT Governance as Behavior

Over the years, the pendulum has tended to swing between centralization and decentralization of IT resources and decision-making. This swing is usually driven by a desire to regain control (centralization) or to ensure that IT and resources are more responsive to local business unit requirements (decentralization). The pendulum swings toward increased centralization when unmanaged devolution results in IT costs going out of control, a lack of integration across corporate systems, and, ultimately, suboptimal investments. On the other hand, excessive centralization usually sees

* PRINCE2 (PRojects IN Controlled Environments) is a process-based method for effective project management. It is a de facto standard used extensively by the UK Government and is widely recognized and used in the private sector, both in the United Kingdom and internationally. The method is in the public domain, offering non-proprietorial best practice guidance on project management.

dissatisfaction across business units with decisions too often subject to political interference and negative impact on customers. When organizations seek the best of both worlds, a federal model [30] is generally implemented.

Conversations around IT governance typically focus on the allocation of accountabilities for decisions related to IT [31]. Governance is an inevitable necessity in a devolved environment, particularly with global organizations. The IT governance structure is the framework that governs decision-making and ensures that all lead to maximizing the return on all IT investments to the organization as a whole. Mechanisms of governance include establishing steering committees and other cross-organizational forums, chargeback, IT awareness events, and co-location of IT and business staff.

What we find, however, is that many CIOs fail to recognize that governance is ultimately about behavior and *not* structure. In their conversations with management colleagues, they talk about establishing committees and other cross-departmental and divisional forums. Hi-Impact CIOs, however, have reframed the agenda to one focused squarely on behaviors. Just as corporate governance seeks to ensure that executive management act in the best interests of shareholders and owners of the business, IT governance should seek that behaviors about information and IT—decisions, protection, usage—are made in the best interests of the organization as a whole. The challenge that many CIOs face is that business executives often do not feel comfortable making what they perceive as IT decisions; and IT itself making decisions that it should not [32].

In emphasizing behavior, for example, that divisional general managers should prioritize IT spend, the Hi-impact CIOs see this as the quest that guides the choice of governance mechanisms to implement. Additionally, they talk to their business colleagues about information as a core resource that requires stewardship, protection, and exploitation. They report that this can often necessitate educating them and agreeing with them the kind of behaviors that should ideally be exhibited. This includes everything from involvement in IT decision-making to information usage.

Most governance frameworks that are promoted, such as COBIT,* focus on "IT governance of IT." They emphasize the *how*, rather than providing a deep understanding of the *why* of governance. What is missing is "enterprise governance of IT." Indeed, one CIO said to us recently that if the IT governance structure that he had recently instituted works, he will be out of a job as business colleagues would take up responsibilities for IT. He also wryly commented that he saw himself in his role for a very long time, reflecting the difficulty he expected to encounter in getting business managers to take on responsibilities.

58.2.8 From Running IT Like a Business to Running IT for the Business

Over the past decade, a popular prescription that has been promoted is for CIOs to be told that to be effective they must run IT like a business [33]. One CIO of a large bank, plagued by problems with IT, recently boasted at a conference that she saw herself as a CEO of her own organization! Hi-Impact CIOs tell us that this not only sends the wrong message but also strongly influences how business colleagues view the IS organization and their behavior toward it. Running IT like a business instills a certain mindset that can be at odds with the real requirements of IT to generate value to the business. The IS organization can be perceived as wishing to be treated like an other supplier; getting involvement and engagement, particularly for project execution, can be difficult. Hi-Impact CIOs also report that there can be issues with funding, particularly for infrastructure investments.

---

* COBIT (Control Objectives for Information and related Technology) is a set of best practices (framework) for IT. Its mission is "to research, develop, publicize and promote an authoritative, up-to-date, international set of generally accepted information technology control objectives for day-to-day use by business managers and auditors." Managers, Auditors, and users benefit from the development of COBIT because it helps them understand their IT systems and decide the level of security and control that is necessary to protect their companies' assets through the development of an IT governance model. See http://www.isaca.org.

The challenge is not to run IT *like a business* but rather *for the business*. While there is a subtle shift in words, it does illustrate firmly where the focus of the CIOs attention should lie. IT exists to support the business in the achievement of its goals and objectives and to deliver information services. This entails identifying opportunities for innovation, better business integration, and ways to increase customer value. The Hi-Impact CIO acknowledges that when he spends money it is on behalf of the business and for its benefit.

58.3 Conclusion

Few can argue against the importance of IT today. Most businesses could not survive for very long without their IT systems. Yet the history of IT in many organizations is disappointing [34].* We also know that generating business value from IT, both operationally and strategically, is a shared responsibility but that non-IT staff do not always feel comfortable or confident making what they perceive to be IT decisions and getting involved in IT initiatives. Hi-Impact CIOs recognize this and to improve involvement and engagement have engineered subtle shifts in their conversations with CxO colleagues. These shifts establish a new agenda for the CIO, one built around conversations focused on: co-evolution, business priorities, value realization, shaping change, business capability, information exploitation, IT governance as behavior and running IT for the business.

While each shift might seem insignificant, together they represent a fundamental transformation in their dialogue with business colleagues. CIOs report that the outcome is a more rewarding discourse with business colleagues, but more importantly increases the value their organizations generate from IT investments. Language is important. Some CIOs have already embraced this new agenda. The clear message is that CIOs should look at the language that they use when interacting with their CxO colleagues. This might also change the outcomes they are seeking to achieve from these conversations. What my evidence suggests is that in so doing they are likely to get a better response from their business colleagues.

Appendix 58.A: About This Research

Over the past 3 years we have spoken to over 100 CIOs about various aspects of the role and the challenges that they face as CIO. We have also spoken to CxOs about IT and their expectations for CIOs. Many of these interviews have been recorded and transcribed. We have also engaged in in-depth discussions with participants on the Cranfield IT Leadership Program, an executive development program for CIOs and senior IT executives, where findings as reported in this chapter have been presented to test their validity. Publications from this research base include: T. Gerth and J. Peppard, "How newly appointed CIOs take charge," *44th Annual SIMposium*, Dallas, TX, October 2012; J. Peppard, C. Edwards, and R. Lambert "Clarifying the ambiguous role of the chief information officer," *MIS Quarterly Executive*, Vol. 10, 2011, pp. 197–201.

Information Technology Management Frameworks: An Overview and Research Directions

Hillol Bala
Indiana University

V. Ramesh
Indiana University

59.1 Introduction

Information technology (IT) plays a key transformational role at various levels of our lives and society. There are probably very few organizations on the planet that do not have some form of IT and/or IT-enabled organizational processes or routines. Research has repeatedly shown the positive impacts of IT on outcomes at various levels of analysis: country, society, organization, community, and individual (Banker et al. 2011; Brynjolfsson and Hitt 1996; McAfee and Brynjolfsson 2008; Venkatesh et al. 2010). For instance, Dewan and Kramerer (2000) found significant positive impacts of IT on the GDP (Gross Domestic Product) of developed countries. Recent research has found positive influence of IT on organizational outcomes (e.g., Mithas et al. 2011, 2012). In the practitioner literature, although challenges related to the management of IT function have been highlighted (e.g., Heller 2009; Luftman and Ben-Zvi 2011; Wailgum 2009), it is generally well acknowledged that IT has a positive influence on an organization and its members (McAfee and Brynjolfsson 2008; Peppard and Ward 2005). Notwithstanding such general agreements about the favorable role of IT, organizations constantly face challenges related to the effective and efficient management of IT functions for long-term, sustainable organizational benefits.

Challenges associated with managing IT functions were first recognized by organizations in the 1980s when they were concerned about the quality and consistency of services they were getting from their IT units (Arraj 2010; Whittleston 2012). In the 1990s and 2000s, organizations continued to face

challenges related to IT management as they attempted to justify and recoup the significant investments they had made for IT. Senior executives had started to question the business value of IT and impacts of IT on organizational productivity and other key performance indicators (KPIs; Brynjolfsson 1993; IT Governance Institute 2003). During this time, academic research reported a phenomenon widely known as the *IT productivity paradox* that captured the notion that despite high investments in IT, organizations failed to realize any measurable benefits from these investments (Brynjolfsson 1993; Brynjolfsson and Hitt 1996). Although later research, particularly at the organizational level, has shown positive impacts of IT on organizational outcomes, it has underscored the importance of effective and efficient management of IT function in organizations (Aral and Weill 2007; Dewan et al. 2007; Dos Santos et al. 2012).

As IT becomes an integral part of today's organizations and the *IT landscape*—the assemblage of IT-related infrastructure, systems, processes, and service components—becomes increasingly more complex, organizations face continuous challenges related to how their IT landscape should be managed and governed so that they are able to leverage their IT capabilities to achieve organizational goals. *IT management frameworks*—a set of best practice-based industry frameworks to manage various facets of organizational IT—have received widespread acceptance by organizations that attempt to manage the complexity of IT landscape and mitigate associated challenges. The diffusion and the widespread popularity of these frameworks have also been catalyzed by the changing operating environment of organizations (Ross et al. 2006). For instance, organizations have started facing intense local and global competition in recent years, and they have wanted to find ways to gain operational efficiency and strategic advantage. Further, organizations are affected by the changes in society and the world caused by the emergence and widespread diffusion of transformational technologies, such as social media and mobile technologies, and significant shifts in global political and economic landscapes. Many organizations are now able to expand their operations in countries that were not accessible even in 1980s. These organizations now face challenges associated with global distribution of resources and distributed execution of processes. Consequently, it has become imperative for such organizations to find ways to achieve and sustain operational efficiency and other organizational goals. Effective management of IT has been touted as one of the key ways to achieve such efficiency and organizational goals.

This chapter provides an overview of IT management frameworks with a particular focus on frameworks that support three specific IT management areas: (a) *IT governance*, (b) *IT service*, and (c) *IT security*. We briefly discuss the underlying principles and processes of these frameworks. In particular, we highlight the richness that these frameworks offer with respect to managing IT provisions, processes, activities, resources, and metrics to help organizations achieve their organizational goals. In addition to providing an overview of these frameworks, we also discuss the impacts of these frameworks on IT management practices using examples of organizations that gain by implementing these frameworks and associated practices. Finally, we offer a set of research directions that can leverage the richness of these frameworks. We focus on future research that, we believe, will have significant implications for theory and practice related to IT management. To our knowledge, this chapter is a first attempt to reduce the gap between IT management practices and research by offering a prognosis of current practice and calling for actionable future research.

59.2 Emergence of IT Management Frameworks

Although IT management frameworks have been around since the 1980s, the popularity of these frameworks among senior IT and business executives has increased in the late 1990s and early 2000s as many organizations started receiving benefits from implementing these frameworks. In recent years, organizations that develop and promote these frameworks have released updated versions of these frameworks in order to keep up with the complexity of today's organizational contexts and operating environments. Further, some of these frameworks have received recognition from international standards bodies such as the International Organization for Standardization (ISO) and the United Nations (Zhang and Chulkov 2011). Although IT management frameworks can be

TABLE 59.1 Overview of IT Management Frameworks

IT Management Frameworks	Definition	Example
IT governance frameworks	Frameworks that help organizations define and manage leadership and organizational structures and processes to ensure that the organization's IT sustains and extends the organization's strategies and objectives (IT Governance Institute 2003)	• COBIT (Control Objectives for Information and Related Technology)[a]
IT service management (ITSM) frameworks	Frameworks that help organizations ensure that the IT services are aligned to the business needs and actively support them (Cartlidge et al. 2007)	• ITIL (Information Technology Infrastructure Library)[b] • ISO 20000
Information security management (ISM) framework	Frameworks that offer best practice recommendations on information security management, risks, and control within the context of an overall information security management system (ISMS) that defines a set of policies related to IT security and risks (IT Governance Institute 2008a)	• ISO/IEC 27000[c] series
IT project management frameworks	Frameworks that provide standardized methodology, guidelines, rules, and characteristics for IT project management (Project Management Institute 2012)	• PMBOK (Project Management Body of Knowledge) • PRINCE2 (Projects in Control Environments 2)

[a] COBIT is a registered trademark of ISACA and ITGI (IT Governance Institute).
[b] ITIL is a registered trademark of the Office of the Government Commerce in the United Kingdom and other countries.
[c] ISO stands for International Organization for Standardization and IEC stands for International Electrotechnical Commission.

classified and grouped in many different ways, we broadly classify them into four categories in keeping with the core objective(s) of these frameworks: (a) *IT governance frameworks*, (b) *IT service management (ITSM) frameworks*, (c) *information security management (ISM) frameworks*, and (d) *IT project management frameworks*. It is important to note that some of these frameworks have provisions and processes that conceptually and operationally overlap with that of the other frameworks. For example, it is possible that frameworks that are primarily developed and implemented for IT governance purposes can have provisions and processes related to ITSM and vice versa. Similarly, ITSM frameworks may have provisions and processes related to ISM. Nonetheless, we use this broad classification to categorize these frameworks because it offers a useful organizing principle for the task. Table 59.1 provides a brief overview of these four types of frameworks and examples.

IT governance is a process of specifying the decision rights (i.e., who holds the rights to make IT-related decisions) and accountability (i.e., who is held responsible for an organization's decision-making about IT assets) to encourage desirable behavior in using IT (Weill and Ross 2004). An IT governance framework helps an organization direct and control the current and future IT endeavors. Such a framework also helps an organization meet high-level IT goals such as alignment of IT with the business, realization of promised benefits, use of IT to exploit opportunities and maximize benefits, responsible use of IT resources, and appropriate management of IT-related risks (IT Governance Institute 2003). Consistent with the practitioner literature associated with the widely used IT governance frameworks and prior academic research on IT governance, we suggest that IT governance should be an inseparable component of corporate governance and a core responsibility of the board of directors and senior executives (IT Governance Institute 2003; Ross and Weill 2002; Sambamurthy and Zmud 1999; Weill and Ross 2004; Zhang and Chulkov 2011). It should not be an isolated discipline or activity performed by the IT leadership. Instead, it should be an integral part of corporate governance and should be considered a core competence of an organization (Agarwal and Sambamurthy 2002; Jewer and McKay 2012; Willcocks et al. 2006). In a nutshell, an IT

governance framework offers a set of principles, processes, activities, and measures that help organizations develop and sustain IT governance-related core competencies and outcomes.

The underlying driver of ITSM frameworks is the recognition that IT services are crucial, strategic organizational assets. Consequently, organizations must invest appropriate levels of resources into the support, delivery, and management of these critical assets and the IT systems that underpin these assets (Cartlidge et al. 2007; Gacenga et al. 2010; Kneller 2010; Whittleston 2012). The primary objective of ITSM is to ensure that IT services are aligned to the organizational needs and actively support them. ITSM can be defined in various ways—(a) as a *practice* related to planning, designing, developing, delivering, and optimizing IT services, (b) as a *discipline* that offers processes, methods, activities, measures, functions, and roles that are needed to deliver IT services, and (c) as a *profession* that defines a set of skills needed to deliver high-quality IT services (Kneller 2010; Rai and Sambamurthy 2006). An ITSM framework ensures that effective implementation, management, and support of IT services, that is, IT processes, systems, and resources, will lead to organizational effectiveness in at least two ways: (a) by reducing business disruptions, loss of productive hours, and costs, and (b) by increasing revenue, improving public relations, and achieving its core objectives (Cartlidge et al. 2007). An ITSM framework offers an extensive body of knowledge, capabilities, skills, and best practices for providing value to customers in the form of IT services (Cartlidge et al. 2007; Kneller 2010; Whittleston 2012). It is intended to provide a wide range of benefits to an organization, such as increased satisfaction with IT services, improved service availability, financial savings, strategic advantage, and improved decision-making (Cartlidge et al. 2007; Gacenga et al. 2010; Kneller 2010; Whittleston 2012).

Benefits from effective IT governance practices and service management do not come without risks (Chen et al. 2011; Kouns and Minoli 2010; Spears and Barki 2010). An IT risk is a potential exposure facing an organization as a result of any aspect of the IT environment—that is, IT assets, resources, organization, or processes (Westerman and Hunter 2007). There are numerous examples of IT risks and associated adversarial outcomes faced by today's organizations. In fact, there is hardly an organization that has not faced some type of challenges associated with IT risks such as system failure, network outage, and security breaches. Organizational IT risks can be broadly grouped into four dimensions (Westerman and Hunter 2007): *availability* (i.e., keeping existing processes running and recovering from interruptions), *access* (i.e., ensuring that authorized people have access to information and facilities they need), *accuracy* (i.e., providing accurate, timely, and complete information), and *agility* (i.e., implementing new strategic initiatives). Although IT risks are primarily related to issues connected to IT systems and people (e.g., employees), prior research has found that these risks do not necessarily arise from technical and/or people issues. These risks typically arise from high-level organizational factors, such as ineffective IT governance, uncontrolled complexity in the IT landscape, and inattention to IT-related risks (Westerman and Hunter 2007). These factors clearly indicate a need for a framework and/or standard practices to manage and control IT risks. An ISM framework is intended to provide an organization a mechanism for effective management and control of IT risks. An ISM framework is also expected to help an organization manage all aspects of IT risks through a set of processes, skills, and best practices. In conjunction with managing and controlling IT risks, an ISM framework ensures the confidentiality, integrity, and availability of an organization's assets, information, data, and IT services (Clinch 2009; Kouns and Minoli 2010).

In the remainder of this section, we discuss three widely used IT management frameworks: (a) *COBIT*, an IT governance framework, (b) *ITIL*, an ITSM framework, and (c) *ISO/IEC 27000*, a family of information security standards. In keeping with the core objective of this chapter to focus on frameworks to manage IT functions in organizations, we do not discuss IT project management frameworks because IT projects do not necessarily represent ongoing activities or functions of an IT organization.

59.2.1 IT Governance Framework: COBIT

COBIT is one of the most widely implemented IT governance frameworks. It was developed in 1996 by the Information Systems Audit and Control Association (ISACA) and the IT Governance Institute

(ITGI) as a standard for IT security and control practices (Violino 2005). ISACA that currently goes by its acronym only is an international professional association that deals with IT governance and serves more than 95,000 constituents (members and professionals holding ISACA certifications) in more than 160 countries. While COBIT was first developed as a framework for IT audit and control, it evolved over time and has become the *de facto* guide for defining, implementing, and managing various aspects of IT governance in organizations. Since 1996 COBIT has had five major releases, with COBIT 5 being the most recent version that was released in 2012. COBIT 5 is considered the most comprehensive release of COBIT frameworks because it consolidates and integrates the earlier version of COBIT (4.1) and two other frameworks developed by ISACA—Val IT 2.0 and Risk IT—and draws from ISACA's IT Assurance Framework (ITAF) and the Business Model for Information Security (BMIS). It also aligns with other IT management frameworks such as ITIL, PMBOK, ISO, and PRINCE2 (ISACA 2012).*

59.2.1.1 Overview of COBIT 5

COBIT 5 is based on five core principles (Figure 59.1). These principles dictate the processes and metrics that define the core structure of the framework. COBIT 5 is a value-driven framework that offers a comprehensive goals cascade linking the framework with a set of organizational and IT-related goals. This goals cascade essentially offers a mechanism to translate stakeholder needs (e.g., benefits realization, risk optimization, and resource optimization) into specific, actionable, and customized organizational goals, IT-related goals, and enabler goals. This translation provides the ability to set specific goals at every level and area of an organization in support of the overall goals and stakeholder requirements. Although COBIT 5 allows organizations to set their own goals at every level, it offers a comprehensive set of goals for various levels that organizations can adopt as baseline outcomes and customize them as needed to fit with their unique requirements and contexts.

Building on the core principles shown in Figure 59.1, COBIT 5 prescribes a comprehensive set of 37 processes related to organizational IT activities that are under the purview of IT governance. Figure 59.2 illustrates these core processes of COBIT 5 that are divided into two broad categories: (a) *governance* of enterprise IT and (b) *management* of enterprise IT. As shown in Figure 59.2, the governance processes

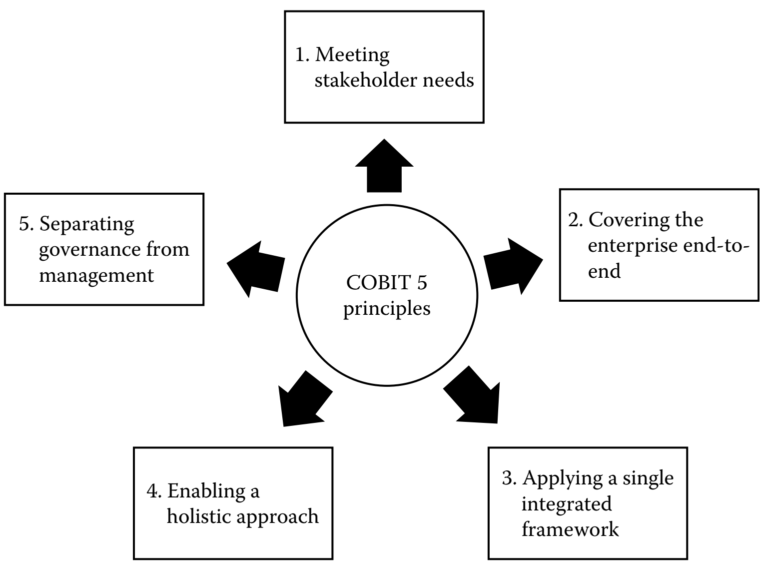

FIGURE 59.1 COBIT 5 principles. (Adapted from http://www.isaca.org/COBIT/Documents/COBIT5-Laminate.pdf)

* We discuss the relationship among IT management frameworks later in this chapter.

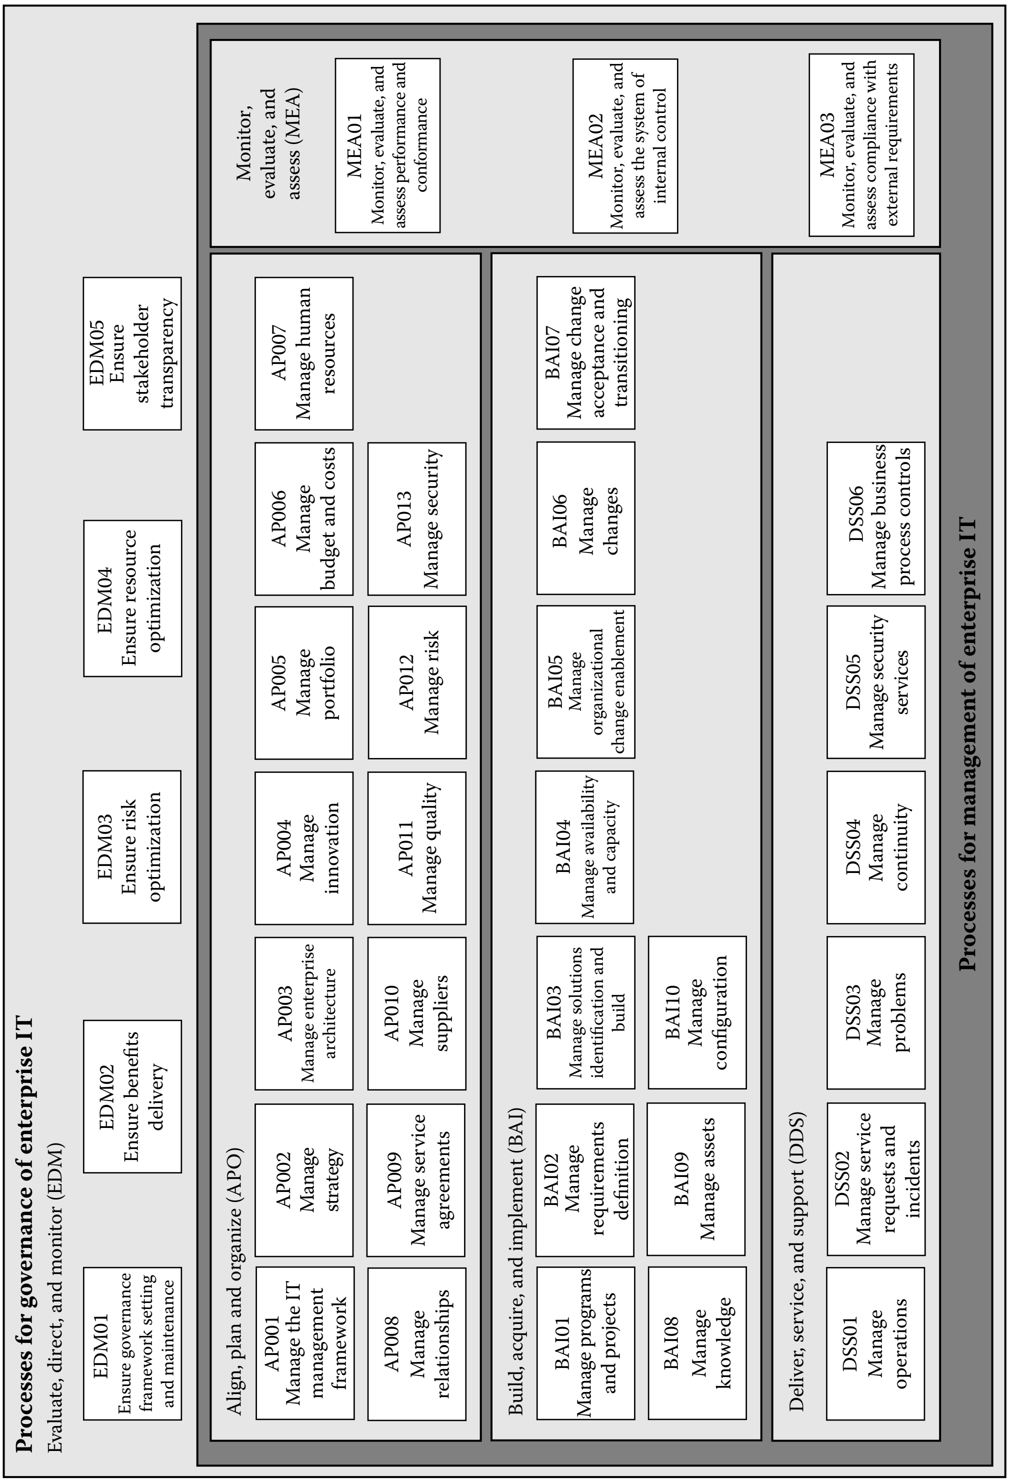

FIGURE 59.2 COBIT 5 process reference model. (Adapted from http://www.isaca.org/COBIT/Documents/COBIT5-Laminate.pdf)

deal with the stakeholder governance objectives such as value delivery, risk optimization, and resource optimization, and include practices and activities aimed at evaluating strategic options, providing direction to IT, and monitoring the outcome. These activities are broadly categorized as *Evaluate, Direct, and Monitor (EDM)* processes or practices. Management processes deal with practices and activities that cover the responsibility areas related to PBRM (plan, build, run, and monitor) of enterprise IT. These processes are grouped into four broad categories: (a) *Align, Plan, and Organize (APO)*, (b) *Build, Acquire, and Implement (BAI)*, (c) *Deliver, Service, and Support (DSS)*, and (d) *Monitor, Evaluate, and Assess (MEA)*. COBIT 5 provides a comprehensive guideline related to each of these governance and management processes with respect to how it should be implemented (i.e., activities, inputs, and outputs), its goals and metrics, its relationship with IT-related goals, and key governance practices (who holds the decision rights and is held accountable for decision-making).

COBIT 5 is expected to offer a set of strategic and operational benefits to organizations that implement these processes (see Figure 59.2). These benefits include, but are not limited to: (a) maintaining high-quality information to support business decisions, (b) achieving strategic goals and realizing business benefits through the effective and innovative use of IT, (c) achieving operational excellence through reliable, efficient application of technology, (d) maintaining IT-related risk at an acceptable level, (e) optimizing the cost of IT services and technology, and (f) supporting compliance with relevant laws, regulations, contractual agreements, and policies (ISACA 2012). However, these intended benefits cannot be achieved if organizations fail to define and manage the enablers that help organizations achieve enterprise and IT-related goals. COBIT 5 provides guidelines related to how each of these enablers—that is: (a) principles, policies, and frameworks, (b) processes, (c) organizational structure, (d) culture, ethics, and behaviors, (e) information, (f) services, infrastructure, and applications, and (g) people, skills, and competencies—should be implemented, monitored, and measured to ensure effective implementation of COBIT and a high degree of alignment between IT and business.

59.2.2 IT Service Management Framework: ITIL

ITIL is considered the *de facto* industry framework for ITSM processes, practices, and delivery. ITIL has been around for more than 20 years. It was originally developed in the early 1980s by a government agency in the United Kingdom, Central Computer and Telecommunications Agency (CCTA), that later merged into the Office of Government Commerce (OGC), a division under the U.K. Treasury. The CCTA and later the OGC recognized the need for developing and implementing standardized processes for IT service delivery. As noted earlier, such standardization was needed because of the increasing complexity in the IT landscape characterized by obsolescence of mainframe-centric infrastructure, distributed computing, and geographically dispersed resources (Arraj 2010). Although such a landscape afforded organizations the potential for increasing flexibility and processing capabilities, it inevitably created a scope for inconsistent IT service delivery across the organization. In an attempt to reduce this inconsistency, organizations started looking for a framework that would help standardize IT service design and delivery.

ITIL was originally published as a collection of 31 associated books covering various aspects of ITSM practices and provisions. The principle of the ITIL framework was based on a process-based view of controlling and managing operations pioneered by W. Edwards Deming using a plan-do-check-act (PDCA) cycle. The early version of ITIL was adopted by many large organizations including government agencies in Europe in the 1990s. ITIL quickly became a cornerstone for ITSM by allowing organizations to take a disciplined approach to service support and delivery. As ITIL grew in popularity in Europe and beyond, and the IT landscape started to become complex, there was a need to revise the early version of ITIL to develop a more closely connected and consistent set of books. ITIL V2 was introduced in the 2000–2001 time period by consolidating the initial library of 31 books to a manageable set of seven books that were more accessible and affordable (Cartlidge et al. 2007; Whittleston 2012). ITIL V2 became the *de facto* standard for ITSM practices around the world. By the mid-2000s, it had been adopted and implemented

by thousands of organizations as a basis of effective ITSM practices (Cartlidge et al. 2007; Kneller 2010). In 2007, ITIL V3 was introduced by enhancing and consolidating ITIL V2. ITIL V3 consists of five core books covering the lifecycle of IT services. In addition to these five core books, there is a sixth book, the *Official Introduction* that offers an overview of the five books and an introduction to ITSM as a whole. The core books and the additional complementary publications by the U.K. OGC offer detailed guidance on the implementation of IT service lifecycle and associated processes, principles, practices, and methods (Cartlidge et al. 2007).

59.2.2.1 Overview of ITIL V3

As noted earlier, ITIL V3 adopted a lifecycle approach to IT services. Figure 59.3 illustrates the core stages of this lifecycle and associated processes. The lifecycle starts with the stage of *service strategy* in which IT and business strategists collaborate to develop IT service strategies that support and align with business strategy practices (Cartlidge et al. 2007; Kneller 2010). Some of the key processes related to service strategy are strategy generation, service portfolio management, and demand management. Once the IT service strategies are defined, an IT organization is in a position to enter the second stage, *service design*, in which the IT organization designs the overarching IT architecture and each IT service to meet business objectives practices (Cartlidge et al. 2007; Kneller 2010). Some key processes related to service design are service catalog management, service level management, capacity management, information security management, and IT service continuity management. The third stage,

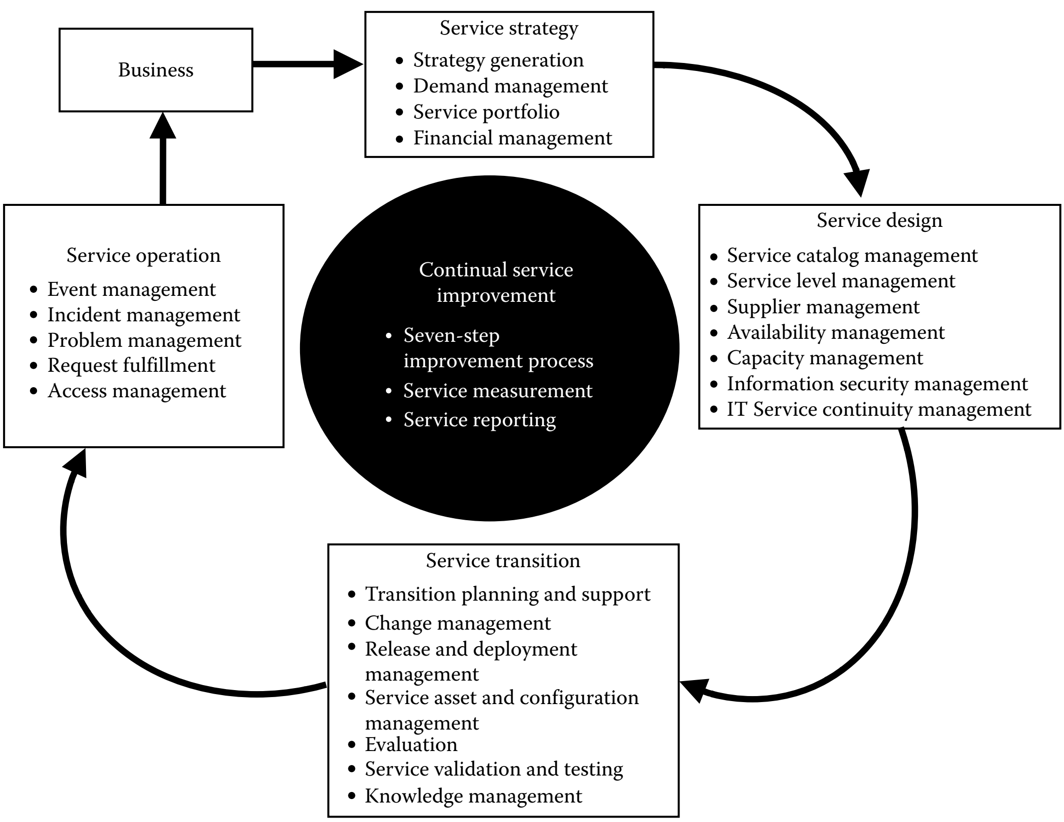

FIGURE 59.3 ITIL V3 process framework. (Adapted from Cartlidge, A. et al., *An Introductory Overview of ITIL® V3*, The UK Chapter of the itSMF, United Kingdom: itSMF Ltd., 2007.)

service transition, helps an IT organization migrate its designed IT services into live environments. The key processes in this stage help an IT organization manage and control new services or changes in IT services. Some of these processes are change management, release and deployment management, transition planning and support, and service assets and configuration management. Once the transition is done, the fourth stage, *service operation*, helps an IT organization deliver and support operational IT services in such a way that they meet organizational needs and expectations (Cartlidge et al. 2007; Kneller 2010). The key processes related to service operation are event management, incident management, request fulfillment, problem management, and access management. Finally, the fifth stage, *continual service improvement*, helps an IT organization learn from experience and adopt an approach, which ensures continual evaluation and improvement of the quality of IT services and the overall maturity of ITSM service lifecycle and underlying processes (Cartlidge et al. 2007; Kneller 2010). The key processes related to continual service improvement are seven-step improvement process, service measurement, and service reporting.

The adoption and effective implementation of ITIL V3 are expected to offer several operational and strategic benefits to organizations. These benefits include, but are not limited to, alignment of IT services with organizational priorities and objectives; manageable IT costs; increased business productivity, efficiency, and effectiveness by making IT services more reliable and better; financial savings from improved resource management and reduced rework; effective change management; improved user and customer satisfaction with IT; and improved end-customer perception and brand image (Cartlidge et al. 2007; IT Governance Institute 2008a; Kneller 2010; Whittleston 2012). However, organizations may not be able to garner these benefits if they fail to implement ITIL effectively. We discuss challenges related to ITIL implementation later in this chapter.

59.2.3 Information Security Framework: ISO/IEC 27000 Series

Although the need for an information security framework and associated policies was felt by organizations in the 1980s and 1990s, it was not until 1995 when the first well-received best practice standard for ISM was published. Known as BS 7799, it was developed by the U.K. Government's Department of Trade and Industry (DTI). BS 7799 had two parts—the first part, BS 7799-1, provided the best practices for ISM and the second part, BS 7799-2, provided specifications and guidance about using information security management systems (ISMS) to manage and control information security in an organization. BS 7799-1 was adopted by ISO as ISO/IEC 17799 in 2000 and was known as the Code of Practice for Information Security Management (Clinch 2009). ISO/IEC 17799 was later revised in 2005. Around this time, organizations across the world started placing significant importance on information security and IT risks because of the operational and strategic value of information and technologies as organizational assets. Recognizing the need for a broad set of standards to support a wide variety of information security-related issues, ISO chose to create a new numbering scheme to accommodate a whole of family of information security standards. Consequently, the ISO/IEC 27000 family of information security standards was created and ISO 17799 was renamed ISO/IEC 27002 and BS 7799-2 became ISO/IEC 27001 (Clinch 2009).

ISO and IEC developed ISO/IEC 27000 as a family of information security standards to specify the fundamental principles, concepts, and vocabulary for the ISO/IEC 27000 series of documents. It is important to note that the scope of ISO/IEC 27000 framework is not limited to IT-related risks and security. These standards also provide best practices and guidelines to manage any aspects of information (e.g., data, documents, messages) that an organization and its members may produce and consume. The key concept of the ISO/IEC 27000 standard is the planning, development, implementation, and operation of a certifiable ISMS. According to these standards, an ISMS provides a model for establishing, implementing, operating, monitoring, reviewing, maintaining, and improving the protection of information assets to achieve business objectives based upon a risk assessment and the organization's risk acceptance levels designed to effectively treat and manage risks (ISO/IEC 2009). Individual standards within the ISO/IEC 27000 family

TABLE 59.2 ISO/IEC 27000 Standards

Standards	Description
ISO/IEC 27000	Provides an overview of and/or introduction to the ISO/IEC 27000 standards as a whole and the specialist vocabulary used in this family of standards
ISO/IEC 27001	Provides the details of the Information Security Management System (ISMS) requirements standard; ISMS provides the underlying foundation for the ISO/IEC 27000 standards and is used as the baseline to certify organizations that are ISO/IEC 27000 compliant
ISO/IEC 27002	Provides the code of practice for information security management describing a comprehensive set of information security control objectives and a set of generally accepted good practice security controls
ISO/IEC 27003	Provides guidance on implementing ISO/IEC 27001 (i.e., ISMS)
ISO/IEC 27004	Provides guidance on information security management measurement
ISO/IEC 27005	Provides details of an information security risk management standard
ISO/IEC 27006	Provides a guide to the certification or registration process for accredited ISMS certification or registration bodies
ISO/IEC 27007	Provides a guide to auditing ISMS
ISO/IEC 27008	Provides guidelines for the auditing of technical security controls
ISO/IEC 27010	Provides guidance on information security management for intersector and interorganizational communications
ISO/IEC 27011	Provides a guideline for information security management for telecommunications organizations (also known as ITU X.1051)
ISO/IEC 27013	Provides guidance on the integrated/joint implementation of both ISO/IEC 20000–1 (derived from ITIL) and ISO/IEC 27001 (ISMS)
ISO/IEC 27014	Provides guidelines for the governance of information security
ISO/IEC 27015	Provides information security management guidelines for organizations in the financial services industry
ISO/IEC 27016	Provides guidelines for the economics of information security management
ISO/IEC 27017	Provides guidelines for the information security aspects of cloud computing
ISO/IEC 27018	Provides guidelines for the privacy aspects of cloud computing
ISO/IEC 27019	Provides guidelines related to information security for process control in the energy industry
ISO/IEC 27031	Provides an ICT (information and communication technology) focused standard on business continuity
ISO/IEC 27032	Provides guidelines for cybersecurity
ISO/IEC 27033	This standard will replace the multipart ISO/IEC 18028 standard on IT network security
ISO/IEC 27034	Provides guidelines on information security for IT applications
ISO/IEC 27035	Provides guidance on information security incident management
ISO/IEC 27036	Provides security guidelines for supplier relationships
ISO/IEC 27037	Provides guidelines for digital evidence
ISO/IEC 27038	Provides specifications for digital redaction
ISO/IEC 27039	Provides guidelines for concerns intrusion detection and prevention systems
ISO/IEC 27040	Provides guidelines on storage security
ISO/IEC 27041	Provides guidelines on assurance for digital evidence investigation methods
ISO/IEC 27042	Provides guidelines on analysis and interpretation of digital evidence
ISO/IEC 27043	Provides guidelines on digital evidence investigation principles and processes
ISO 27799	Provides health sector–specific ISMS implementation guidance based on ISO/IEC 27002

Source: Adapted from http://www.iso27001security.com/html/iso27000.html

provide guidelines and best practices for planning, development, implementation, and operation of an ISMS and associated ISM components (e.g., IT network security or cybersecurity). Table 59.2 provides a list of ISO/IEC 27000 standards that are either published or under development.

59.2.3.1 Overview of ISO/IEC 27001 and 27002

Although individual standards within the ISO/IEC 27000 family provide valuable guidelines for managing and controlling different aspects of information security in an organization, there are two

standards—ISO/IEC 27001 and ISO/IEC 27002—that offer the key documents related to requirements and practices associated with ISMS. ISO/IEC 27001 specifies the requirements for establishing, implementing, operating, monitoring, reviewing, maintaining, and improving a documented ISMS, using a continual improvement approach (DiMaria 2012). This standard provides a detailed discussion of the following areas related to ISMS: general requirements, implementation process, management and operation, maintenance and improvement, documentation requirements, management responsibility, resource provision, training awareness, internal audits, management, and continual improvement (Clinch 2009). It also offers mapping with other standards, such as OECD (Organization for Economic Cooperation and Development) principles, ISO 9001 (i.e., a *de facto* quality management standard), and ISO 14001 (an environmental management standard) for organizations that have implemented these other standards (Clinch 2009; DiMaria 2012).

ISO/IEC 27001 is intended to be implemented and used along with ISO 27002, also known as Code of Practice for Information Security Management (DiMaria 2012). ISO/IEC 27002 offers guidance on interpretation and implementation of the list of specific security controls within ISO 27001 (DiMaria 2012). The standard provides a set of security controls in different areas of information security management and offers guidance on how organizations can achieve these control objectives. Figure 59.4 illustrates these security controls grouped into 15 core areas of information security management (e.g., risk management, asset management, access control, software development, incident management, business

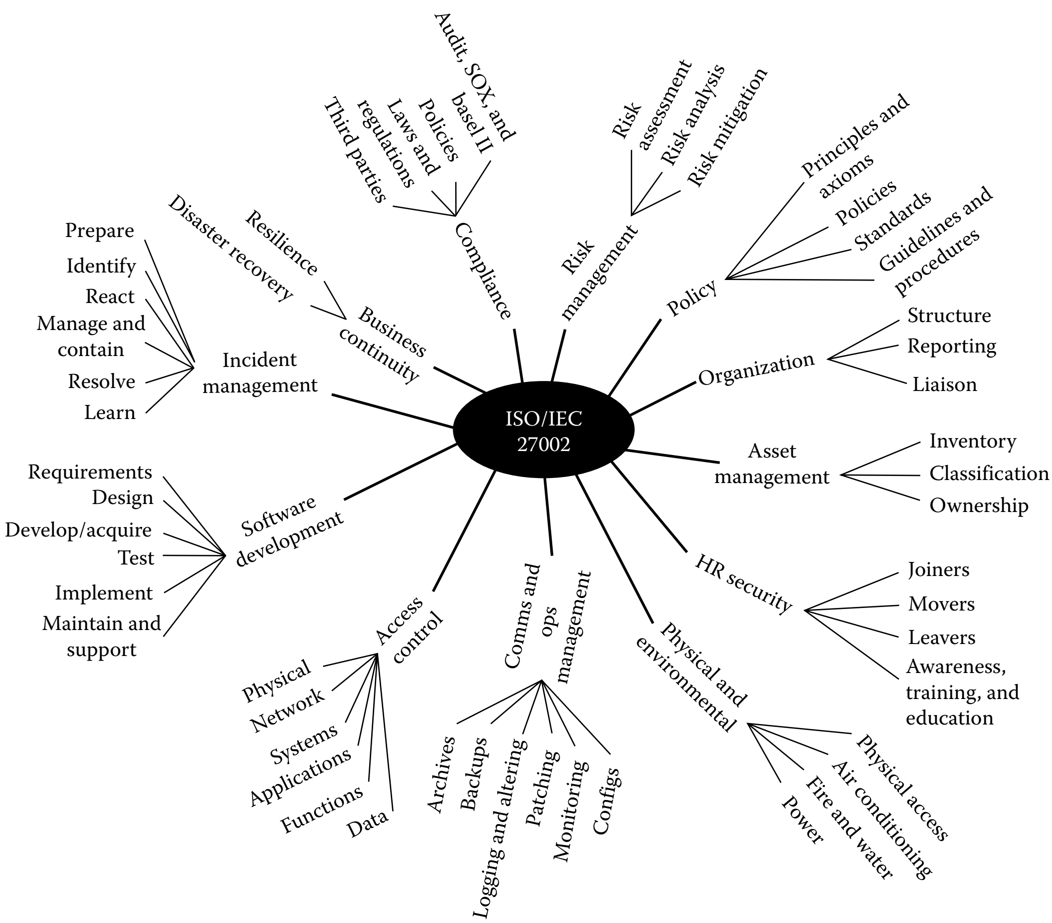

FIGURE 59.4 ISO/IEC 27002 control objectives. (Adapted from http://www.iso27001security.com/html/27002.html)

continuity, and compliance). Together, ISO/IEC 27001 and ISO/IEC 27002 offer several key business benefits to organizations when implemented: increased credibility and trust; improved partner, customer and stakeholder confidence; organizational and trading partner assurance; demonstration to competent authorities that the organization observes all applicable laws and regulations; competitive advantage and market differentiation; and reduced regulation costs (Clinch 2009; DiMaria 2012).

59.2.4 Relationships among the IT Management Frameworks

It is important to note that although IT management frameworks were developed to meet different organizational needs with respect to managing IT assets and capabilities, these frameworks have noticeable overlaps and striking similarities. Indeed, these frameworks have processes and metrics that are conceptually similar. For instance, COBIT 5 has specific processes (and associated subprocesses, activities, inputs, outcomes, and metrics) related to managing service agreements (APO09), availability and capacity (BAI04), changes (BAI06), operations (DSS01), and service requests and incidents (DSS02) that are conceptually similar to some key processes of ITIL V3, such as service level management, availability management, capacity management, change management, event management, and incident management (see Figures 59.2 and 59.3). Similarly, both COBIT 5 and ITIL V3 have processes related to security management, the core focus of ISO/IEC 27000 standards. Although these conceptually similar processes have common goals, these processes are operationally different and offer differential levels of granularity with respect to subprocesses, activities, inputs, and outputs. For example, COBIT offers high-level processes and metrics that are relevant to an entire IT organization and provides a mechanism to align IT and organizational goals. While there are processes, metrics, and IT goals related to IT service and security in COBIT, these are typically not as comprehensive as they are in ITIL or in ISO/IEC 27000 because COBIT focuses on many other IT processes in addition to processes related to IT service and security (IT Governance Institute 2008a,b). Another key difference is that COBIT focuses on the maturity and control of high-level IT processes, whereas ITIL focuses on executional details of service-related processes. Unlike COBIT and ITIL, ISO/IEC 27000 frameworks do not offer detailed processes related to information security management. Instead, it offers a set of control objectives that organizations can incorporate in their security policy to protect their information assets (see Figure 59.4).

Although there are significant differences among IT management frameworks, it is important to note that these frameworks typically do not contradict each other and it is possible for them to peacefully coexist in an organizational setting. In fact, there have been significant efforts in the practitioners' community regarding how these frameworks can be aligned and mapped with each other so that organizations can maximize implementation benefits (e.g., Clinch 2009; IT Governance Institute 2008a,b). These efforts have led into multiple publications by industry associations that provided comprehensive mapping of these frameworks with each other to help organizations implement an IT management framework without sacrificing the benefits they receive from other frameworks that they might have already implemented. For instance, the IT Governance Institute (2008b) offered a detailed mapping of how these frameworks complement each other's different IT governance domains and provided guidelines on how organizations can align these frameworks for organizational benefits. Clinch (2009) offered a detailed overview of how ITIL and ISO/IEC 27000 standards are aligned with each other.

Consistent with the efforts in practitioner literature about the peaceful coexistence of IT management frameworks, we suggest that IT organizations are in a unique position to leverage the IT management frameworks for organizational benefits. Adoption, effective implementation, and mapping of these frameworks will help IT organizations manage and control IT as a routine part of organizational activities. As shown in Figure 59.5, an IT governance framework will help an organization establish a clear standard, consistent procedures, and unambiguous practices regarding the overall IT function of an organization that is aligned with organizational-level activities, goals, and strategies. Once an IT governance framework is established and in effect, other frameworks will be able to leverage its processes, metrics, and control objectives, and deliver additional values to specific areas—e.g., service management,

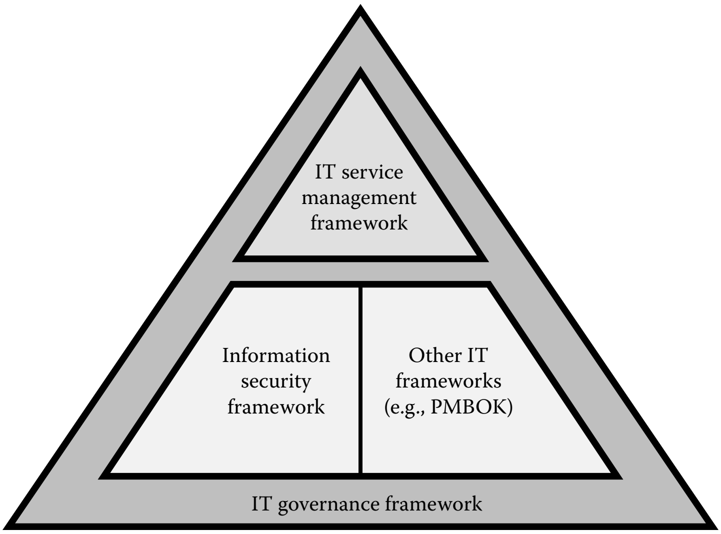

FIGURE 59.5 Relationship among IT management frameworks.

security management, and project management, related to the IT functions of an organization. We view an IT governance framework as an underlying platform that enables an organization to embrace other more specific frameworks that provide much deeper consideration of different elements, such as policies, processes, measurements, and improvements related to specific areas of IT. Together these IT management frameworks will help organizations manage their IT functions effectively and efficiently, and ensure a high degree of IT-business alignment and convergence (King 2010).

59.3 Impacts of IT Management Frameworks

IT management frameworks have profound impacts on how organizations manage and control their IT functions. As noted earlier, these frameworks have gained widespread popularity in the late 1990s and early 2000s. During this time, organizations had started making significant investments in IT and sought ways to ensure positive returns from these investments. There was a need to develop and implement frameworks that could help organizations better manage IT functions, justify investments in IT, and garner benefits from IT. Although there has been limited scientific evidence regarding the impacts of IT management frameworks on organizational outcomes (with a few exceptions that we highlight in this section), the practitioner literature is replete with anecdotal evidence and cases about the positive impacts of IT management frameworks on organizations and its members. In this section, we discuss impacts of IT management frameworks on practice with a particular focus on the measurable benefits that organizations are able to gain from implementing these frameworks. We also discuss the current status of adoption and implementation of these standards and associated challenges.

59.3.1 IT Governance Framework: COBIT

59.3.1.1 Adoption and Implementation of COBIT

Given that COBIT 5 was released recently (2012), our discussion of COBIT adoption and implementation is primarily based on COBIT 4.1 and earlier releases. There are numerous organizations around the world that have implemented different aspects of COBIT and received significant benefits. We will provide a list of some major organizations that have implemented COBIT in the following section. It is important

to note that although COBIT offers a comprehensive set of goals, processes, metrics, actions, and implementation details, it allows organizations to fully customize these different components to meet unique organizational needs. COBIT does not enforce implementation of any of these components in any specific sequence. In order to help senior executives make effective decisions about components of COBIT, it offers different tools such as management guidelines and benchmarking tools using a maturity model framework. Further, ISACA and IT Governance Institute offer training programs for organizations that are interested in implementing COBIT. Overall, COBIT offers flexible implementation provisions allowing senior executives to select the specific goals, processes, and metrics that are applicable in their organizational context, determine the cost-benefit ratio of adopting these components, and implement the components that will be most beneficial to their organizations.

We note that implementation of COBIT is not an easy journey. It requires radical changes in senior executives'—both IT and non-IT—mindset regarding the value of IT in their organizations. Given that COBIT is a process-oriented framework that defines management and control of IT assets and decisions, it requires changes in existing processes in order to derive benefits from implementation. Further, COBIT implementation is a resource-intensive process because of changes in organizational processes, and the need for advisory services and extensive training during implementation. In addition to challenges related to change and resource management during implementation, there are other reasons for COBIT implementation failure. Ramanathan (2007) highlighted some of these reasons: (a) absence of a formal, documented strategy during implementation, (b) weak communication of strategy (i.e., there might be major communication gaps between IT and business, and the value of implementation may not be properly communicated to the stakeholders), (c) technology-driven projects (i.e., COBIT is essentially an organizational framework and should not be driven by technology), (d) lack of project ownership by business and senior executives, and (e) informal IT performance assessment (i.e., IT organization is not willing to embrace a formal performance assessment).

59.3.1.2 Impacts of COBIT on Practice

COBIT has been implemented by major organizations such as Oracle, MetLife, Blue Cross Blue Shield, ScotiaBank, National Stock Exchange of India, U.S. Department of Veterans Affairs, U.S. Department of Defense, European Parliament, Harley-Davidson, UNISYS Corporation, Fidelity Investments, Allstate, and Charles Schwab. These organizations have received numerous benefits from COBIT (ISACA 2012). For instance, Oracle was able to use COBIT matrices and mapping documents to make various IT frameworks fit together. It was also able to leverage the concepts in the COBIT-related materials to create discussion of health and maturity self-assessments, provide a line of sight between its activities and its business goals, bring predictability and reliability to how the IT group plans and manages the work across the enterprise, and complement its corporate planning cycle with an IT management cycle (ISACA 2012). Similarly, COBIT helped Unisys standardize its IT strategy to support global operations, align the IT infrastructure with the company's overall business strategy, and help with Sarbanes-Oxley compliance (ISACA 2012). The U.S. Department of Veterans Affairs (VA), a government agency, was able to create a new organizational structure for centralized IT management based on COBIT that provided a framework for IT governance plans, structures, and investments at the VA (ISACA 2012). Recently, Rouyet and Spauwen (2011) suggested that COBIT can help align green business strategy with IT strategy. For example, they suggested that COBIT processes and metrics are flexible enough to align with business goals related to efficient energy use, public image aligned to environmental concerns, and environmental regulatory compliance.

59.3.2 IT Service Management Framework: ITIL

59.3.2.1 Adoption and Implementation of ITIL

There has been an increasing global trajectory of adoption and implementation of ITIL since 2004. Although ITIL was widely used in Europe in the 1990s and early 2000s, awareness and proliferation

related to ITIL within North American organizations started to accelerate between 2004 and 2006 (O'Donnell 2011). The adoption and implementation of ITIL are now considered mainstream; a majority of the Fortune 500 corporations have adopted and implemented some form of ITIL (O'Donnell 2011). A study conducted by the Forrester Group in 2011 revealed that about 24% of U.S. organizations have formally embarked on ITIL-based programs more than 5 years ago. These programs were less than 5 years old for the remaining 76% of organizations (Mann 2012). Although effective implementation of ITIL hinges on different technological, organizational, and environmental factors, industry reports have found that senior executives in the organization are the most influential drivers of successful ITIL programs, followed by the core ITSM team that manages the IT service lifecycle in the organization (O'Donnell 2011).

There are several challenges associated with ITIL implementation. Ho (2008) noted that resistance to ITIL is often rooted in fear, and suggested that the key to alleviating this resistance is education. As implementation of ITIL requires commitment to a multi-year project, it is often met with resistance by IT employees (directly) as well as non-IT employees (indirectly). Ho (2008) listed a set of *ITIL fears,* a major source of resistance to ITIL implementation, such as fear of change (i.e., unknown consequences of ITIL implementation), fear of measurement (i.e., a perceived loss of control), fear of perceived process rigidity (i.e., ITIL processes can be perceived to be inflexible), fear of cost (i.e., a large investment is required to implement ITIL), and fear of complexity (i.e., ITIL typically introduces new roles, processes, and complexity in organizations).

Even if an organization is able to overcome these fears through training and other interventions, there are possible implementation mistakes that can still prevent organizations from garnering benefits from ITIL implementation (Guglielmo 2008; Mann 2012; Kneller 2010). For example, organizations may design and develop IT services that do not fit with the organizational processes or do not meet organizational needs. In many cases, organizations fail to understand and take account of the ongoing operational cost that ITIL processes require. Many organizations take into consideration the one-off project cost for ITIL implementation and do not recognize the continual service-improvement stage of the IT service lifecycle. Consequently, these organizations fail to recognize the annual cost of ownership for each IT service (Kneller 2010). In many cases, organizations take a "shortcut" approach to implementing ITIL. These organizations fail to recognize that ITIL implementation requires a strategic vision, top management support, a strong business case, an effective communication strategy, and effective control mechanism (Guglielmo 2008; Kneller 2010). ITIL implementation will change the way IT delivers value to the rest of the organization and the way organizations manage IT. There is a need, therefore, to develop effective strategies and interventions to create a service culture and climate throughout the organization (Guglielmo 2008; Kneller 2010).

59.3.2.2 Impacts of ITIL on Practice

There is plenty of anecdotal evidence and numerous case studies that indicate positive impacts of ITIL implementation on organizations and employees. Major organizations from across the world, such as Microsoft, HP, Fujitsu, IBM, Target, Walmart, Staples, Citi, Bank of America, Barclay's Bank, Sony, Disney, Boeing, Toyota, Bombardier, Eli Lilly, and Pfizer, have adopted and implemented ITIL and received significant benefits (Arraj 2010). In addition to these major organizations, there are literally thousands of other organizations of all industries and sizes that have embraced ITIL practices. A recent industry report revealed that ITIL implementation had significant positive impacts on various aspects of IT service delivery and IT employees who deliver IT services (O'Donnell 2011). A survey of 491 ITSM professionals found that ITIL improved quality of IT service (83% of respondents felt so), productivity (85% of respondents felt ITIL improved IT productivity), reputation with the business (65% of respondents felt ITIL was either beneficial or significantly beneficial to improving reputation with the business), and reduce operational cost (41% of respondents felt ITIL helped reduce operational costs by improving the quality of IT services). At the individual level, this report found that ITSM

professionals who are ITIL certified received better salaries than those in the average IT position. In fact, about 70% of ITSM professionals received an increase in their salary over the past year. In the academic literature, Gacenga et al. (2010) conducted a broad-based survey of ITIL implementation in three different countries—Australia, the United Kingdom, and the United States. The results indicated that while ITIL implementation had a positive influence at process-level outcomes, organizations failed to gain broad organizational-level benefits from ITIL because most organizations chose to implement only a subset of ITIL processes.

59.3.3 Information Security Framework: ISO/IEC 27000 Series

59.3.3.1 Adoption and Implementation of ISO/IEC 27000

ISO/IEC 27000 standards are still evolving with many individual standards that are still under development (see Table 59.2). While it is difficult to assess the adoption and implementation drivers and challenges related to these standards, a wide range of organizations have adopted ISO/IEC 27001 and ISO/IEC 27002. These organizations are from different industries and economic sectors, such as IT, software, manufacturing, construction, financial, staffing, shipping, pharmaceuticals, academia, telecom, lottery, security, consulting, insurance, health care, energy, and navigation (IsecT, Inc. 2012; DiMaria 2011). Many government agencies and international organizations, such as the United Nations, have adopted ISO/IEC 27001 for ISM. Given that organizations can receive certification if they comply with ISO/IEC 27001 standards, the number of certificates related to this standard is an acceptable measure of the current adoption level of this standard. There are over 7,200 ISO/IEC 27001 certified organizations in the world as of May 2011 (ISMS International User Group 2012). It is important to note that this total number has potentially been underestimated because reporting of certification status is completely voluntary and many organizations may never report their certification status. Further, ISO/IEC 27001 certificates are issued by multiple certification bodies, so there is no central database of organizations that have adopted these standards and are certified.

59.3.3.2 Impacts of ISO/IEC 27000 on Practice

Although we do not have accurate and complete data regarding the adoption of the ISO/IEC 27001 standard, we found that certifications have been increasing steadily at a rate of about 1000 per year (ISMS International User Group 2012). Again, reporting of certification is voluntary and it is thus possible the rate of increase is underestimated. Such an increasing trajectory of certifications suggests that many organizations that adopted this standard have received benefits from it. Nonetheless, there has been a dearth of academic and practitioner literature related to the impacts of ISO/IEC 27000 standards on organizations. We found a few cases that illustrated how ISO/IEC 27000 standards helped organizations achieve favorable organizational goals (British Standards Institution 2012). For instance, Cleardata, a document scanning and archiving company in the United Kingdom, needed to develop and implement an ISM framework to reassure its clients that it would manage their information and data security to the highest of standards. Cleardata needed to develop a structured framework to ensure that security objectives were met, compliance with laws and regulations was guaranteed, and new business and customer trust was gained. When they adopted ISO/IEC 27001 and got certified, Cleardata was able to win multiple contracts as a direct result of certification. In a different context, a government agency, the NHS Purchasing and Supply Agency of the Department of Health in the United Kingdom, was able to receive official recognition that its security measures were effective; it had a systematic framework for managing sensitive data, and was able to establish a formal standard for the operations of the IT organization. Following the adoption and certification of ISO/IEC 27001, the Agency never had a security incident caused by a staff member, was able to keep the network virus-free and hacker-free, and was able to encourage stakeholders to share information without any fear of security breach and data loss (British Standards Institution 2012).

59.4 Research Opportunities

We suggest that IT management frameworks provide many fruitful avenues for future research. These frameworks offer rich content with respect to principles, provisions, processes, and metrics that can be leveraged in research. Further, there are a multitude of outcomes (i.e., measures of performance indicators) and potential antecedents to these outcomes offered in these frameworks. These relationships also deliver many interesting and fruitful future research opportunities. Although there is a wide range of such opportunities, we provide a set of research directions that we believe will make significant impacts on both theory and practice related to IT management. In addition to leveraging the frameworks that we discuss in previous sections, we also review prior research in the areas of IT governance, ITSM, and information security to unearth scientific gaps in these research streams.

59.4.1 Review of IT Management Research

The literature on IT governance is rich and mature, and it has been around for almost 30 years. This popular stream of research has offered deep insights on issues related to how IT organizations and IT assets should be structured, managed, and controlled for organizational benefits. There have been several recent reviews of this stream that provide a comprehensive description of what we currently know in this literature (e.g., Guillemette and Pare 2012; Jewer and McKay 2012). These reviews have indicated that much prior research has focused on three broad areas: (a) design, development, and implementation of IT governance framework and/or decision-making structures that IT organizations can use to organize their activities (e.g., Kaarst-Brown 2005; Kaarst-Brown and Robey 1999); (b) antecedents and impacts of IT governance practices on organizational outcomes (e.g., Brown 1999; Sambamurthy and Zmud 1999; Weill and Ross 2004); and (c) the role and competencies of board and/or senior executives (both IT and business) in managing and controlling IT governance processes and activities (e.g., Leidner and Mackay 2007; Nolan and McFarlan 2005).

Notwithstanding the richness of research in these three broad areas, we suggest that the IT governance literature in general has overlooked issues related to various components of IT governance frameworks that are widely used in practice. IT governance frameworks such as COBIT offer rich descriptions of processes and their relationships with IT and organizational goals. Although prior research offered insights on governance structure and form, there has been limited research that incorporates various governance processes from COBIT, categorizes them into theoretically meaningful categories, and examines the impacts of these categories on various aspects of organizational outcomes. Such work will be beneficial to practitioners to justify the investments and efforts in IT governance processes and practices. Further, there has been limited research that focused on the measurement of IT governance effectiveness. Although IT governance frameworks such as COBIT offer a comprehensive set of performance indicators for various processes and practices, it is possible that many of these indicators are not scientifically valid and/or practically useful. Future research may organize these measures into theoretically meaningful categories and scientifically validate them for future research and practice.

Like the IT governance literature, the ITSM literature is mature and has offered insights on various aspects of ITSM practices in organizations. ITSM has been a focal topic in two distinct yet related streams of research. The first stream focuses on issues related to designing, developing, implementing, and managing IT services in organizations (e.g., Bardhan et al. 2010; Montoya et al. 2010). In this stream, researchers have concentrated on how organizations design, implement, and access IT services based on emerging IT services platform and architecture, such as application service providers (ASP), web services, service-oriented architecture (SOA), and cloud computing (e.g., Choi et al. 2010; Mueller et al. 2010; Susarla et al. 2003). This stream also deals with issues such as the impact of IT service sourcing and contracts (e.g., Benorach et al. 2010; Kauffman and Sougstad 2008).

Drawing on the service quality literature from marketing (Parasuraman et al. 1994; Zeithaml et al. 1996), the second stream deals with topics related to conceptualizing and measuring IT service

quality—in particular, the quality of IT functions in organizations (e.g., Kettinger and Lee 2005; Pitt et al. 1995). When IS researchers conceptualized and operationalized IT service quality, similar to the notion of service quality in the marketing literature (Parasuraman et al. 2005), they looked at people-delivered services. The key difference was that IS researchers focused not only on IT services (e.g., hardware and software installation) delivered by an entire IT department of an organization but also on the quality of service related to an individual IT system itself. In fact, Pitt et al. (1995) noted that there are two possible units of analysis for conceptualizing and measuring IS service quality (SERVQUAL)—the entire IT department and a particular IT application. While people-delivered services were the key focus initially in the IS literature, researchers have also examined technology-delivered services such as e-commerce websites (e.g., Parasuraman et al. 2005; Ziethaml et al. 2002).

Research on ITSM has either focused on IT infrastructure issues or the overall IT function of an organization while overlooking the specific ITSM processes that may offer differential value propositions for organizations. More importantly, prior ITSM research has focused primarily on IT-enabled service delivery. We are not aware of any research that highlights other stages of the ITSM life cycle, such as service strategy, service transition, and continual service improvement. These stages offer a set of processes, practices, and metrics that have been mostly overlooked in the extant literature. Further, there has been limited research that examined how ITSM processes and practices can lead to favorable outcomes for an IT organization in particular and the overall organization in general. Finally, prior research has offered a limited understanding of measuring the quality of ITSM practices. While SERVQUAL has provided a broad-based measure of ITSM quality, it is not an objective measure and does not capture the richness that an ITSM framework, such as ITIL, may offer.

The IT security literature gives rich insights on various aspects of ISM in organization, such as compliance, security behaviors, security policy decisions, and risk management. Research in this stream can be grouped into two broad categories. The first category is related to the behavioral issues of ISM such as individual compliance, security behaviors, and user involvement in ISM in organizations (e.g., Bulgurcu et al. 2010; Johnston and Warkentin 2010; Siponen and Vance 2010). This stream provides a comprehensive understanding of individual-level issues related to ISM processes and practices in organizations. For example, Bulgurcu et al. (2010) examined the factors that employees consider when they decide to comply with organizational security policies. The second category of IT security research is related to the development and implementation of organizational policies related to ISM and IT risk management (e.g., August and Tunca 2011; Chen et al. 2011). This stream of research employed both empirical and analytical approaches to unearth factors that have implications for organizational information security policies.

Although IT security research offers insights on both individual behaviors and organizational policies, we suggest that this research does not offer insights on the characteristics of a comprehensive ISMS, and antecedents and outcomes of establishing an ISMS. With the advances of technology and increasing complexity in the IT landscape, we suggest that ISM should be an important stream of IT research that focuses on both theoretical underpinnings related to ISM and practical considerations when implementing ISMS. Further, there has been little or no research that examined the value proposition of ISMS for organizations and scientifically validated the impacts of ISM practices on organizational outcomes.

59.4.2 Suggested Research Directions

Our goal is to offer a set of future research directions that address the gap in the current literature and leverage the richness that IT management frameworks offer. One of the rich components of each of these frameworks is performance measures—key performance indicators (KPIs)—for various aspects of IT management in organizations. For example, COBIT and ITIL frameworks and associated documents offer a comprehensive selection of measures to assess the performance of various processes and activities. These measures are now widely available and generally accepted among senior IT executives as indicators to measure performance of IT functions and services. While prior research has provided

various types of IT function assessment (e.g., Brown and Magill 1994; Chang and King 2005; Saunders and Jones 1992), we suggest that future research could leverage the rich performance indicators that IT management frameworks offer to measure performance of IT function in organizations. Thus, we offer the following opportunities for future research.

Research Opportunity 1: Development of Performance Measures
Development and validation of a new scale of (a) IT service quality measures using the ITIL framework; (b) effectiveness of IT governance practices and processes using the COBIT framework; and (c) effectiveness of ISM practices using the ISO/IEC 27001 and ISO/IEC 27002 standards. Is it possible to develop an overall performance scale for each of these areas, or should there be different scales for practices and processes within each of these areas?

In order to leverage the richness of IT management frameworks, it is important for researchers to dig deeper into the different processes and activities that these frameworks provide. These processes and activities indeed offer a detailed representation of what an IT organization does at strategic, tactical, and operational levels to manage IT functions in an organization and how it attempts to align with organizational activities and strategies. As noted earlier, there has been little or no research that has examined the impacts of these processes on outcomes related to IT and organizations. Given the comprehensive nature of these processes, it is probably not possible to incorporate the processes from an IT management framework in a single research inquiry. Therefore, we suggest that researchers try to categorize these processes into theoretical constructs and operationalize them following the guidelines from respective IT management frameworks. For example, researchers can develop three different categories of ITSM processes—strategic, tactical, and operational—and examine the impacts of these processes on outcomes related to IT and organizations. It is important to note that this categorization should be guided by a theoretical framework. We expect that researchers will be able to develop interesting theoretical constructs based on the IT management frameworks and offer theoretical insights on how these frameworks will influence IT and organizational outcomes. Based on this discussion, we propose the following research direction related to the impacts of different components of IT management frameworks.

Research Opportunity 2: Impacts on Organizational Outcomes
What are the impacts of IT governance/ITSM/ISM processes and activities on IT and organizational outcomes? What processes and activities have the most impacts and why? Is it possible to group these processes into theoretical constructs that will inform current organizational theories?

We suggest that IT management frameworks will have a proximal effect on IT outcomes and a distal effect on organizational outcomes. This distal effect could be mediated by the IT-related outcomes. We believe that these relationships have interesting theoretical implications that researchers should explore in future research. For example, it is important to understand what components of IT management frameworks will have a direct influence on organizational outcomes and what components will have a mediated influence through IT-related outcomes. Such an understanding will help IT organizations focus on certain components to achieve desired outcomes. Further, if researchers could show that certain IT outcomes need to be achieved first before garnering organizational benefits from an IT management framework implementation, IT organizations could focus on specific processes and activities to achieve those IT-related outcomes. Overall, we suggest that the dynamics of the relationship between different components of IT management framework and outcomes (both IT-related and organizational) is a fruitful avenue of future research that will have an immediate impact on practices related to IT management in organizations. Based on this discussion, we propose the following opportunity for future research.

Research Opportunity 3: Impacts of Framework Components on Organizational Outcomes
Do different components of IT management frameworks (e.g., processes and activities) have a direct impact on organizational outcomes such as productivity and profitability (as claimed in practitioner reports) or do they have a mediated impact through IT outcomes? How and why? What are the theoretical mechanisms that explain these relationships?

Gordon and Gordon (2002) discussed the tension between IT function and non-IT functions in organizations during IT service delivery. Both academic and practitioner literatures offer numerous examples of tension and the lack of trust between IT and non-IT functions in organizations. We suggest that IT management frameworks will offer new insights into the understanding of the relationship between IT and non-IT functions. These frameworks have specific processes, activities, and metrics related to how an IT organization should manage change and other IT assets that are exposed to end users and customers who are mostly dealing with non-IT functions. Further, these frameworks have specific goals and processes related to improving user and customer satisfaction. A fruitful area of future research will thus be to look into the issues related to the tension and the lack of trust between IT and non-IT functions and offer mechanisms (e.g., processes, practices, and activities) from IT management frameworks about how to resolve this tension and the lack of trust. Therefore, we offer the following research questions for future inquiries.

Research Opportunity 4: Relationship between IT and Non-IT Functions/Users
What are the most effective components of IT management frameworks to improve user and customer satisfaction and trust between IT and non-IT functions? What are the components that may increase tension between IT and non-IT functions? What are the metrics to assess the relationship between IT and non-IT functions?

We suggest that the effective implementation and practice of IT management frameworks will be a source of competitive advantage. While these frameworks are publicly available, we do not expect that all organizations will be able to equally implement and use them effectively. In fact, prior research has shown that publicly available best practices could be implemented and used differently by different organizations, leading to different outcomes (Bala and Venkatesh 2007; Venkatesh and Bala 2012). Based on this discussion, we suggest that organizations will be able to develop certain capabilities around IT management frameworks. For instance, some organizations will be able to develop capabilities related to effective IT governance (e.g., quick decision-making, formal performance evaluation, and high degree of knowledge sharing between IT and business), whereas other organizations may develop capabilities around ITSM practices. We expect that these capabilities will help organizations achieve favorable outcomes at both IT and organizational levels. Therefore, we offer the following research opportunity related to capabilities stemmed from implementing IT governance frameworks.

Research Opportunity 5: Development of IT Management Capabilities
What are some of the capabilities organizations can develop around IT management frameworks? What are the dimensions of these capabilities? What provisions, processes, and activities will determine and define these capabilities?

In sum, the research opportunities that we discuss here are broad and meant to serve as a guideline for researchers to develop more specific research questions for their research. We believe that these opportunities barely scratch the surface of the potential research space that IT management frameworks may offer. We expect that these opportunities will spur many fruitful research programs in the context of IT management frameworks.

59.5 Concluding Remarks

Our review of both practitioner and academic literatures indicates that although IT management frameworks, such as COBIT, ITIL, and ISO/IEC 27000, have been able to generate a wide range of interests and acceptance among senior executives who are interested in understanding how IT functions in an organization should be governed, managed, operated, and controlled, these frameworks have been conspicuously overlooked in mainstream academic research. While we acknowledge that academic research needs to be theory-driven (as opposed to framework-driven) and needs to offer theoretical insights about a phenomenon of interest, we suggest that IT researchers have a unique opportunity to conduct theory-driven research leveraging the richness of IT management frameworks. Recently, Mithas

et al. (2011) employed the Baldridge criteria, an industry framework to assess performance excellence developed by the National Institute of Standards and Technology (NIST), to conduct theory-driven research, and found strong support for the relationship between information management capability and firm performance. We suggest that IT researchers should undertake similar research in the context of IT management frameworks for at least two reasons.

First, we believe that such research will help the IT research community reduce the theory–practice (and the rigor-relevance) divide that is prominent in IT research. The details about this divide and associated debates have been outlined elsewhere (see for example, Benbasat and Zmud 1999; Constantinides et al. 2012; Davenport and Markus 1999). Recently, Rosemann and Vessey (2008) suggested that relevance for practice can be achieved by producing research that is important to practice, is accessible by practitioners, and can be assessed for relevance through applicability checks (Constantinides et al. 2012; see Rosemann and Vessey 2008 for details related to applicability check). Others have called for conducting high-visibility and high-impact research that has impacts on both theory and practice (e.g., Agarwal and Lucas 2005). In light of these views, we suggest that given the widespread acceptance of IT management frameworks, researchers may have a unique opportunity to help practitioners improve these frameworks and implement them effectively by offering insights from rigorous scientific research. We are not aware of any major scientific studies and associated publications that examined the implementation challenges, appropriate configuration, and impacts of these frameworks. Therefore, we suggest that such research will be able to help the IT research community reduce the gap between theory and practice in the context of IT management by helping practitioners improve the quality of these frameworks and the implementation process.

Second, we believe that the richness of IT management frameworks will help researchers develop valuable theoretical insights related to IT management practices in organizations. There has been much debate about the role of *IT artifact* in IT research. Scholars have called for placing an explicit emphasis on IT artifact in order to enhance the legitimacy of the discipline and to alleviate the *identity crisis* that the discipline currently faces (Benbasat and Zmud 2003; Constantinides et al. 2012; Orlikowski and Iacono 2001). We believe that research based on IT management frameworks will help researchers address this call by offering deep insights on how IT should be managed for organizational benefits. Further, prior research has called for incorporating the role of *contexts* in theory development (Johns 2006; Rousseau and Fried 2001). The components of IT management frameworks, such as processes, activities, inputs, outputs, and responsibility assignments, offer rich contexts to study various aspects of IT management practices in organizations. Researchers will be able to discover boundary conditions of existing organizational theories and offer novel theoretical perspectives leveraging the rich contexts that IT management frameworks may offer. For instance, using the resource-based view (RBV) of the firm theory, prior research has developed a comprehensive set of IT capabilities. While these capabilities are important, IT management frameworks can help researchers extend these capabilities by including other dimensions, such as IT service management capabilities, IT governance capabilities, and information security management capabilities. Overall, we suggest that IT management frameworks may offer opportunities for developing novel theoretical perspectives on IT management activities in organizations.

In conclusion, we reiterate our view that IT management frameworks are important for both theory and practice. We believe that these frameworks are here to stay and will improve over time to help organizations address the key concerns related to IT management (Luftman and Ben-Zvi 2011). Notwithstanding the implementation challenges we discuss in this chapter, there is an increasing trend of adoption and implementation of these frameworks. Therefore, we believe that it is high time to develop fruitful research programs around these frameworks. In this chapter we offer an overview of these frameworks and highlight that these frameworks can coexist peacefully in organizations. We also discuss the impacts of these frameworks on practices based on our extensive review of the practitioner literature. Our major contributions are the discussion of prior research and potential research opportunities based on these frameworks. Our hope is that this chapter will fuel future research and intellectual discourse on popular IT management frameworks.

Acknowledgments

We thank Professor Heikki Topi, Volume Editor, for his thoughtful comments and suggestions to improve the chapter. We thank Dr. Suzanne Van Hove, CEO of SED-IT, and Julie Montgomery, Director of Marketing of Plexent, for their support and encouragement for our project on IT management frameworks. We also thank Professor V. Sambamurthy (Michigan State University) for his guidance in helping us think about future research directions on IT management. Finally, we appreciate Akshay Bhagwatwar's help in the literature review and background research on IT management frameworks.

Sourcing Information Technology Services

Mary Lacity
University of Missouri–St. Louis

Leslie Willcocks
London School of Economics and Political Science

60.1 Introduction

Information technology (IT) sourcing is the acquisition of resources, including human capital resources, to deliver IT services such as application development, application support, systems integration, data management, data center management, telecommunications and network management, and distributed computing (e.g., desktops, laptops, mobile devices, and resources on the cloud). In this chapter, we review the practice of and research on the sourcing of IT services. This chapter is organized around four topics: (1) IT sourcing decisions, (2) the determinants of IT sourcing decisions, (3) IT sourcing outcomes, and (4) the determinants of IT sourcing outcomes (see Figure 60.1).

IT executives make decisions about IT sourcing options and IT sourcing locations, and when outsourcing, decisions about multisourcing versus bundled services, and next-generation sourcing decisions when initial contracts approach expiration. Academic researchers have thoroughly studied the motivations, influence sources, and transaction attributes that determine sourcing decisions. Researchers have also thoroughly studied the outcomes of outsourcing. Overall, the academic evidence finds that outsourcing can deliver value to client organizations, but that it takes a tremendous amount of detailed management by clients and providers to realize expected benefits (Lacity et al. 2010a). Researchers have identified the transaction attributes, contractual governance, relational governance, client-retained capabilities, and provider capabilities that determine IT outsourcing (ITO) outcomes. Despite all that researchers do know about sourcing IT services, there are

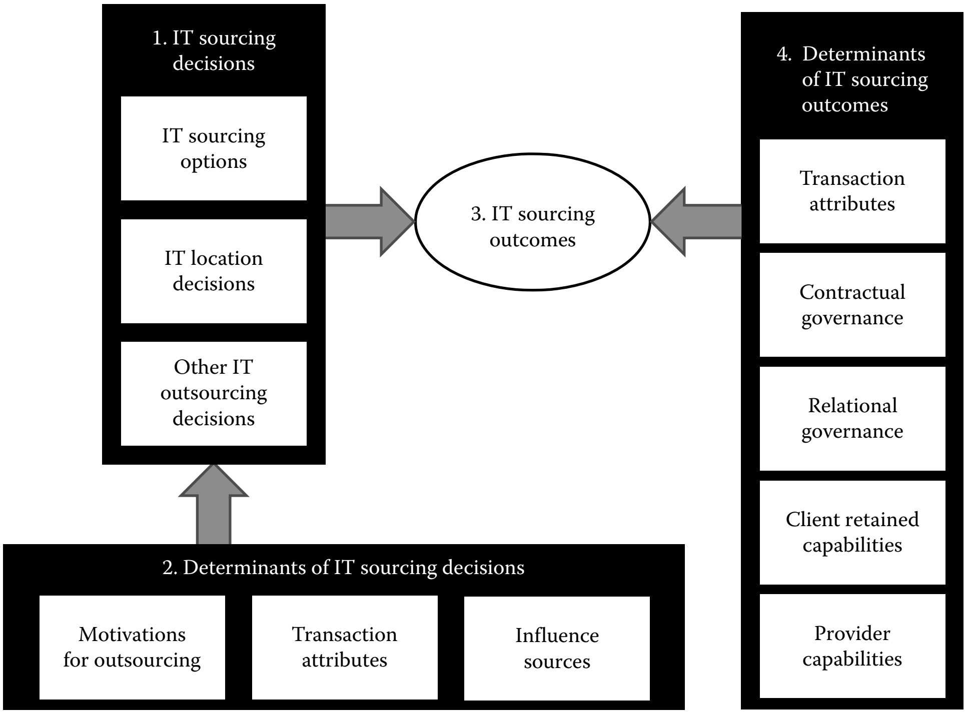

FIGURE 60.1 IT sourcing decisions and outcomes.

still gaps in knowledge and enduring practitioner challenges. Thus, the area of sourcing IT services remains an important topic for research.

60.2 IT Sourcing Decisions

The most fundamental sourcing decision is the "make-or-buy" decision (Williamson 1975). Should organizations insource or outsource IT services? In reality, the make-or-buy decision is more complex because there are many sourcing options, sourcing locations, and providers to be considered. For over a decade, we have argued that a better question is "How can organizations leverage the external services market for business advantage?" (Lacity and Willcocks 2001). Many IT academics, informed closely by both theory and practice, have good answers to this question. In this section, we discuss sourcing options, sourcing locations, and other decisions IT executives consider when sourcing IT services. These choices have different benefits and risks and may require unique practices to ensure positive outcomes.

60.2.1 Sourcing Options

IT executives have numerous sourcing options to consider, including insourcing, staff augmentation, management consulting, shared services, traditional outsourcing, cloud computing, and joint ventures/partnerships (see Table 60.1). The IT sourcing options are not mutually exclusive; many IT organizations use many or even all of these options. Many internal shared services organizations, for example, rely heavily on outsourcing providers. Many client/provider relationships include both staff augmentation (price per full-time equivalent) and fee-for-service pricing components (Fersht et al. 2011). Many joint ventures also have fee-for-service components for the services the venture delivers to the client investor. IT executives provide a portfolio of IT services that, in turn, necessitate a portfolio of sourcing options.

TABLE 60.1 Sourcing Options

Sourcing Options	Description
In-house provision; insourcing	A sourcing option in which the organization owns the IT assets and employs its own IT staff (Lacity and Hirschheim 1995; Hirschheim and Lacity 2000)
Staff augmentation; contract labor	A sourcing option in which an organization buys in low- to mid-level labor to supplement in-house capabilities; the client manages the people, usually at the client site (Ang and Slaughter 2001)
Management consulting	A sourcing option in which an organization buys in high-level expertise to supplement in-house capabilities (Lacity et al. 2003)
Shared services	A sourcing option in which an organization centralizes and standardizes IT delivery (Lacity and Fox 2008; Lacity and Willcocks 2012a)
Traditional outsourcing; fee-for-service outsourcing; exchange-based outsourcing	A sourcing option in which a client pays a fee to a provider in exchange for the management and delivery of specified IT services. The client is in charge of specifying needs and the provider is in charge of managing the resources to deliver those needs (Lacity and Willcocks 1998)
Cloud computing; netsourcing; application service provision	With this utility model, clients pay a usage-based fee to providers in exchange for services being delivered over a network, typically the Internet (Iyer and Henderson 2010; Willcocks et al. 2010b, 2011b)
Joint ventures; strategic partnerships	A specific type of contract entered into by two or more parties in which each agrees to furnish a part of the capital and labor for a business enterprise (DiRomualdo and Gurbaxani 1998; Lacity et al. 2003, 2004)

Insourcing is still the most commonly pursued sourcing option. The annual Society of Information Management survey of Chief Information Officers (CIOs) conducted by Jerry Luftman typically finds that about 33% of an annual IT budget is for internal staff, compared to 9% for consulting services, 15% for domestic contractors/providers, and 3%–4% for offshore providers (Luftman and Kempaiah 2008; Luftman and Zadeh 2011). Increased use of external staff—both domestic and offshore—is growing and obviously gains more public attention than the quieter, yet larger, insourcing practice. Two scholarly works examined insourcing closely (Lacity and Hirschheim 1995; Hirschheim and Lacity 2000). We studied firms that examined the outsourcing market and decided to insource. In some of these firms, the shear threat of outsourcing empowered IT executives to make sweeping—yet unpopular—changes to reduce IT costs on their own through consolidation, standardization, and rationalization of IT resources. The lesson for practitioners is that the external services market serves as a viable competitor that keeps in-house staff motivated.

With *staff augmentation*, an organization buys in low- to mid-level labor to supplement in-house capabilities. In any Fortune 500 company IT headquarters, up to 40% of the staff may be domestic contract laborers who work alongside IT employees. Organizations use a staff augmentation model to meet fluctuations in demand for IT work, to access scarce technical skills, and to avoid the HR headaches associated with employment. Staff augmentation is one of the most expensive options if IT executives buy labor from urban cities in developed countries. Staff augmentation is one of the least expensive options if firms buy labor offshore or from nonurban (rural) areas (Lacity et al. 2010b). Ang and Slaughter (2001) have one of the best studies comparing IT contractors to permanent employees. In a survey, they found that contract workers have lower levels of loyalty, trustworthiness, obedience, and performance than permanent workers. In interviews, they found that contract workers had lower task variety, identity, significance, autonomy, and feedback relative to permanent workers.

Management consulting is a short-term sourcing option in which an organization hires an advisory firm or consulting firm typically for help with new strategic initiatives, like creating a global standard enterprise resource planning (ERP) platform or developing a sourcing strategy. This sourcing option brings in external energy, signals clear commitment to the strategic initiative, and reduces political resistance. Although management consultancy has several major risks, the two most significant ones are potential cost escalation and lack of sustainability because the provider has no long-term commitment.

The result can be a lessened sense of accountability and a lack of alignment between the parties. Furthermore, expertise and knowledge may leave when the consultant leaves (Lacity et al. 2003).

Shared service is defined by Accenture as "the consolidation of support functions (such as human resources, finance, IT, and procurement) from several departments into a standalone organizational entity whose only mission is to provide services as efficiently and effectively as possible" (Accenture 2005). Shared service is one of the most important IT management trends and was listed as one of the seven habits of effective CIOs (Andriole 2007). The recent downturn in the economy has intensified the pressures for organizations in both the public and private sectors to reduce costs, shed headcount, and to do more and more with fewer resources. Shared services are seen as a powerful practice for relieving these pressures. Shared services offer the promises of lower costs, tighter controls, improved service levels, and scalability. Studies have shown, however, that not all organizations achieve the benefits they expect from shared services; many shared service initiatives take years to implement and result in meager cost savings (Lacity and Willcocks 2012a). Among all the advanced practices for successfully implementing shared services, change management may be the most important and the most lacking practice. Based on our case studies, we found that creating shared services requires a coordinated integration of four change programs: business process redesign (BPR), organizational redesign, sourcing redesign, and technology enablement (Lacity and Fox 2008; Lacity and Willcocks 2012a).

Traditional outsourcing is the most common form of outsourcing and has grown each year it has been tracked, with the exception of a slight dip in 2009. Gartner estimates that the global ITO market in 2012 is worth $309 billion and Booz Allen and Hamilton estimate that ITO is growing at 10% per year.* With this option, a client pays a fee to a provider in exchange for the management and delivery of specified IT services. The client is in charge of specifying needs, and the provider is in charge of managing the resources to deliver those needs. Much of the academic literature on ITO falls under this category, and there have been hundreds of published studies, which we reviewed in Lacity et al. (2010a). The fee-for-service model works best when (1) clients have a good understanding of their baseline service levels, costs, and volumes, (2) requirements are stable, (3) a capable provider is selected, and (4) the contract is designed to benefit both parties. However, fee-for-service contracts are notoriously inflexible, and changes are difficult to handle because client/provider incentives are not aligned. Change will usually harm one of the parties. In successful relationships, both parties resolve disputes caused by change by focusing on what is fair, rather than by what is designated in the contract (Lacity and Willcocks 2012b).

Cloud computing is the idea of buying IT services like a utility. The concept of buying IT as a utility service is not new—time sharing was indeed the first outsourcing model back in the 1960s. During the dot com boom, application service provision (ASP) was a business model in which providers hosted and rented standard applications to clients over the Internet. ASP was one way small organizations could access expensive software—like enterprise resource planning software by SAP or Oracle—while avoiding high infrastructure costs, support costs, or hefty software license fees. ASP burst when the dot com bubble burst. Clients liked the idea of renting rather than owning IT resources, but providers had difficulty generating revenues because the value of client contracts was too small, the duration of client contracts too short, the marketing costs to educate clients about ASP too high, the margins from reselling propriety software too thin, and the transaction costs of serving so many needy clients too high (Kern et al. 2002). Today, cloud computing is the reincarnated, supercharged version of ASP. Cloud computing is one of the fastest growing markets in the ITO/business process outsourcing (BPO) space. According to Gartner, cloud computing was a $68.3 billion industry in 2010. IDC and Harris and Nunn predict that cloud-based service revenues will grow globally between $44 billion and $60 billion in 2013. Gartner predicts it will reach $148.8 billion by 2014.

* Size of market figures by various consulting firms is in the public domain. Gartner data is also reported in October 2009 issue of *Accenture Outlook: The Journal of High Performance Business*; Booz, Allen, and Hamilton found in Outsourcing for Virtuosos, Webinar with Vinay Couto and Ashok Divaran; Booz, Allen, and Hamilton, http://www.strategy-business.com/media/file/Outsourcing_for_Virtuosos-webinar.pdf

Despite the tremendous public attention to cloud computing, it cannot achieve yet the plug-and-play simplicity of electricity (Willcocks et al. 2011b).

Joint ventures/strategic partnerships are not very common, but the scale and scope of these deals garnered significant media attention, particularly during the 1990s (DiRomualdo and Gurbaxani 1998). In joint ventures, the provider investor intends to sell the client's assets or excess capacity to third parties and share the revenues with the client investor. Examples of these deals included Swiss Bank and Perot Systems, Commonwealth Bank and EDS, Xerox and EDS, and Delta Airlines and AT&T. These deals did not work as planned. The providers had their hands full just servicing the client investors' operational needs. In addition, clients frequently oversold the value and portability of their assets. The IT deals we studied all reverted to fee-for-service relationships or were completely terminated. We found more success with joint ventures/strategic partnerships in other back office services including procurement, human resource management, claims, and policy administration (Lacity et al. 2003, 2004).

60.2.2 Sourcing Locations

IT executives have to make location decisions—where will IT staff be located? Options include domestic, offshore, nearshore, rural, or global (see Table 60.2). Location strategies may or may not involve outsourcing. For example, offshore may involve offshore outsourcing, joint ventures, strategic partnerships, or captive centers (insourcing). Location decisions are often based on a country's business, financial, and human resource attractiveness. A *country's business attractiveness* is the degree to which a country is attractive to organizations because of favorable business environmental factors such as economic stability, political stability, cultural compatibility, infrastructure quality, and security of intellectual property (IP) (e.g., Doh et al. 2009; Malos 2009). A *country's financial attractiveness* is the degree to which a country is attractive because of favorable financial factors such as labor costs, taxes, regulatory, and other costs (e.g., Doh et al. 2009; Malos 2009). A *country's human resource attractiveness* is the degree to which a country is attractive because of favorable people skills and availability factors such as size of labor pool, education, language skills, experience, and attrition rates (e.g., Mehta et al. 2006; Malos 2009).

A country's attractiveness can change rapidly, as happened with the political upheavals in Egypt in 2011, which halted international investment in Egypt's ITO services export market. For this reason, we have advised that clients base location decisions on the organization's strategic objectives and overall commitment to certain destinations (Lacity and Rottman 2008). For example, one aerospace company selected Malaysia as their IT offshore destination because they hoped to sell planes in that country. The Malaysian government requires that some of the manufacturing be done in Malaysia, and the IT presence would certainly help to meet that requirement. Another hardware company selected China because they hoped to sell computers there. Other participants selected offshore locations where they have existing manufacturing or R&D facilities. The existing facilities serve as a launch pad, with current employees serving as guides to the country, providers, and culture (Rottman and Lacity 2006).

TABLE 60.2 Sourcing Location Decisions

Sourcing Locations	Description
Domestic	IT service delivery center located in the same country as the client's business users
Offshore	IT service delivery center located on a different continent than the client's business users (Lacity and Rottman 2008; Oshri 2011)
Nearshore	IT service delivery center located in a nearby country (such as a U.S. client being serviced from a Canadian delivery center) (Carmel and Abbott 2007)
Rural	IT service delivery center located in a rural community (Lacity et al. 2011a)
Global	IT service delivery centers located in several countries (Willcocks and Lacity 2006)

Domestic location of IT staff is pursued when organizations value close proximity between business users and IT staff. Close physical proximity is associated with better service quality, faster response time, better domain understanding, easier communications, and lower transaction costs (Lacity and Rottman 2008). However, domestic staff—whether employees, contract labor, or domestic outsourcing—is the most expensive location option in high-cost locations like urban U.S. or U.K. cities.

Offshore location of IT staff is pursued when organizations seek lower costs, sunrise-to-sunrise services, access to IT talent, and/or geographical risk mitigation. Western-based organizations frequently select India, the Philippines, Eastern Europe, or China as offshore destinations, particularly for the lower cost and talent availability. The offshore outsourcing market has been estimated to be about $80 billion to $100 billion market, with India representing the largest share of IT and business service exports. Despite noise suggesting that India will lose its edge due to rising wages, the Everest Group (2011) predicts that India will maintain its lead for 12 years under a pessimistic scenario and for 23 years under an optimistic scenario. Preferred venues change based on a mix of location attractiveness factors, and a recent development has seen offshore venues such as India also re-outsourcing work to countries like Egypt and China. Research has found that locating staff offshore can deliver on many of its promised benefits (Lacity and Rottman 2008), but researchers have also found that offshore locations pose additional challenges when compared to domestic locations. For example, captive centers or offshore outsourcing are more challenging because of time zone differences (Carmel 2006), increased efforts in knowledge coordination (Kanawattanachai and Yoo 2007; Kotlarsky et al. 2008) and boundary spanning (Levina and Vaast 2008; Mahnke et al. 2008), the need for more controls (Choudhury and Sabherwal 2003; Lacity and Rottman 2008), cultural differences (Carmel and Agarwal 2001; Krishna et al. 2004; Carmel and Tjia 2005), defining requirements more rigorously (Gopal et al. 2002), and difficulties in managing dispersed teams (O'Leary and Cummings 2007; Oshri et al. 2007). Some of these issues are so difficult to manage that practitioners are turning to nearshore alternatives (Carmel and Abbott 2007).

Nearshore location of IT staff is pursued when the organization expects to benefit from one or more of the following constructs of proximity: economic, geographic, temporal (time zone), cultural, linguistic, political, and historical linkages (Carmel and Abbott 2007). Nearshore locations are selected primarily because of lower costs, but may be preferred to "offshore" because the proximity requires less time and money to travel and provides time zone overlap between the business and IT services organizations. For U.S. organizations, the North American Free Trade Agreement (NAFTA) facilitates nearshoring because it is easier to obtain visas from NAFTA partners than it is to obtain visas for India-based staff (Carmel and Abbott 2007).

Rural location of IT staff is an emerging niche trend in several countries, including the United States, India, China, and Israel. We estimated the US ITO "pure-play" rural outsourcing market to be about $200 million in 2011 (Lacity et al. 2011a). The Rockefeller Foundation sizes the global impact sourcing market—which is primarily a rural market—at $4.6 billion in 2010 (Lacity and Willcocks 2012a). The main appeals of rural locations are lower wages and higher retention rates because few or no competitors exist to poach talent. Within the United States, rural locations can reduce IT costs by up to half compared to urban locations like New York City (Lacity et al. 2010b). In India, despite the global economic recession, global demand for Indian ITO and BPO services is still very strong and consequently Indian providers are still experiencing 14%–22% turnover in urban areas (The Everest Group 2011). By building delivery centers in Tier 3 cities, Indian organizations achieve lower costs and attrition rates. Chinese providers also cited lower costs, but not necessarily lower attrition rates, by locating in Tier 3 cities. Specifically, they reported that labor costs are up to 50% lower and real estate costs are 70%–90% lower in Tier 3 cities compared to Tier 1 cities (Lacity et al. 2011a). The major downsides of rural locations are scalability and workforce availability.

Global location, having IT service delivery centers located in several countries, is the norm for large, international companies. Large global companies locate IT services globally using a combination of sourcing options discussed earlier, including captive centers, fee-for-service outsourcing, and joint partnerships. One U.S. global financial services company we studied has various captive centers, joint ventures, and

TABLE 60.3 Other Sourcing Decisions

Sourcing Decisions	Description
Multi-sourcing vs. sole sourcing	The decision pertaining to the number of providers to engage (Lacity and Willcocks 2001, 2012a; Willcocks et al. 2010a)
Next Generation	Before ITO contracts expire, IT executives decide whether to keep the current provider, switch providers, or backsource IT services (Whitten and Leidner 2006; Willcocks et al. 2011a)

fee-for-service relationships with 14 Indian providers. This network of providers enabled the company to quickly adapt to the immense surge in mortgage applications during the refinancing boom. As the refinancing boom burst, the company was able to immediately scale back resources—all without affecting their domestic IT headcount (Lacity and Rottman 2008). Global outsourcing providers like Accenture and IBM can provide vast geographic coverage for their clients. For example, our current research on high-performance BPO is studying how Accenture provides Microsoft with coverage in 94 countries and 37 languages.

60.2.3 Other Outsourcing Decisions

If IT executives decide to outsource, there are two additional decisions that follow: How many providers? What do we do when the contract expires? As an existing outsourcing contract approaches maturity, organizations must decide what to do next: renegotiate with the incumbent provider, switch providers, bring the service back in-house, or terminate the service altogether (see Table 60.3).

Multisourcing or bundled services. When outsourcing, organizations also have to decide about the number of providers to engage. Multisourcing has the advantages of choosing best-of-breed providers, mitigating the risks of relying too much on one provider, and helping clients adapt in changing environments. Multisourcing has several disadvantages, including increased transaction costs as organizations manage more providers, interdependencies, and interfaces (Lacity and Willcocks 2001). The major advantages of bundled services from a single provider include simplified procurement, simplified governance, fewer transaction costs, and economies of scale and scope. But bundled services increase switching costs and the risks of relying on one provider (Willcocks et al. 2010a; Lacity and Willcocks 2012a).

Next generation. Most ITO clients are in their second, third, and even fourth generation of ITO relationships. As contracts begin to mature, organizations need to decide what to do next. Should they renegotiate a contract with the incumbent provider? Switch providers? Backsource by bringing the IT function back in-house? In one of our early surveys of U.S. and U.K. CIOs, we found that 32% of client organizations had canceled one or more outsourcing contracts. Of these half-switched providers, one-third brought the IT service back in-house and 11% ended up renegotiating the contract with the incumbent provider due to prohibitive switching costs (Lacity and Willcocks 2001). More recently, Willcocks et al. (2011a) surveyed Australian CIOs and found that 65% renegotiated with the incumbent, 30% switched providers, and 5% backsourced. In Willcocks et al. (2011a), the authors prescribe how CIOs prepare for the next generation based on hundreds of case studies.

60.3 Determinants of IT Sourcing Decisions

In addition to studying the types of sourcing decisions organizations make, academics have thoroughly studied the determinants of sourcing decisions, including the motives, transaction attributes, and influence sources (see Figure 60.1). These determinants are introduced later (see Lacity et al. 2010a for deeper coverage).

60.3.1 Motives for Sourcing Decisions

Researchers have studied at least 27 motives or reasons driving sourcing decisions. The most frequently found motives are listed in Table 60.4. Research has consistently found that sourcing decisions are

TABLE 60.4 Top Motives for Sourcing Decisions

Sourcing Motives	Description
Cost Reduction	An organization's need or desire to reduce or control Information Systems (IS) costs (e.g., Barthélemy and Geyer 2004)
Focus on Core Capabilities	An organization's desire or need to focus on its core capabilities (e.g., Lacity et al. 1994; Linder 2004)
Access to Skills	An organization's desire or need to access provider skills/expertise (e.g., Lacity et al. 1994; Clark et al. 1995)
Business/Process Improvements	An organization's desire or need to help improve an organization's business, processes, or capabilities (DiRomualdo and Gurbaxani 1998)
Technical Improvements	An organization's desire or need to gain access to leading edge technology that is available through the providers but may not be available in-house (e.g., Sobol and Apte 1995)
Political Reasons	A client stakeholder's desire or need to promote personal agendas such as eliminating a burdensome function, enhancing their career, or maximizing personal financial benefits (e.g., Lacity et al. 1994; Hall and Liedtka 2005; Chakrabarty and Whitten 2011)
Concern for Security/IP	An organization's concerns about security of information, transborder data flow issues, and protection of intellectual property (e.g., Khalfan 2004; Walden 2005; Rao et al. 2006)
Fear of Losing Control	An organization's concerns about losing control over IT (e.g., Patane and Jurison 1994; Collins and Millen 1995)

primarily driven by the need to reduce overall IT costs, usually by at least 10%–15% (IAOP 2010; Lacity et al. 2010a). Research has also found that the greater the fear of losing control of the service, concern for security, or fear of losing IP, the more likely an organization chose insourcing. Besides cost savings, research has found that organizations expect ITO to deliver a number of additional business benefits, including one or more of the following: ability to redirect in-house staff on more strategic activities, access to scarce skill sets, service quality improvements, business process improvements, and technology improvements (Lacity et al. 2010a).

60.3.2 Transaction Attributes

Researchers have examined at least 14 transaction attributes as potential determinants of IT sourcing decisions. Four attributes were commonly found to drive IT sourcing decisions: uncertainty, critical role of IT, transaction costs, and business risks (see Table 60.5). Higher values for any of these transaction attributes were associated with higher frequencies of insourcing (Lacity et al. 2010a).

60.3.3 Influence Sources

Researchers have studied the extent to which mimetic, normative, and coercive influences determine sourcing decisions within organizations. Among these, only mimetic influences were repeatedly examined and found to significantly influence sourcing decisions. Mimetic influences are influences that

TABLE 60.5 Transaction Attributes Affecting Sourcing Decisions

Transaction Attributes	Description
Uncertainty	The degree of unpredictability or volatility of future states as it relates to the definition of IT requirements, emerging technologies, and/or environmental factors (Williamson 1991a,b; e.g., Poppo and Zenger 2002; Aubert et al. 2004)
Critical role of IT	The degree to which an organization views IT as a critical enabler of business success (e.g., Teng et al. 1995; Saunders et al. 1997; Straub et al. 2008)
Transaction costs	The effort, time, and costs incurred in searching, creating, negotiating, monitoring, and enforcing a service contract between buyers and providers (Williamson 1991b; Ang and Straub 1998)
Business risk	The probability that an action will adversely affect an organization (Lacity et al. 2010a)

arise from the perception that peer organizations are more successful and by modeling themselves based on peer organizations, the mimicking organization aims to achieve similar results (e.g., DiMaggio and Powell 1991; Ang and Cummings 1997). In the ITO context, researchers found that client organizations were influenced to outsource IT based on peer institutions that successfully outsourced IT (Lacity et al. 2010a).

Researchers have also examined the determinants of next-generation decisions. Whitten and Leidner (2006) found that both economic and relationship constructs are important determinants of second-generation outsourcing decisions. Clients renewing contracts report high levels of product quality, service quality, relationship quality, and switching costs. Clients that switched providers report high product and service quality but low relationship quality and switching costs. Clients that brought back IT in-house report low levels on all four variables.

60.4 IT Sourcing Outcomes

Many researchers have examined the outcomes of ITO and the determinants of ITO outcomes. In contrast, we are aware of only two studies that examined the effects of insourcing decisions—the decision to source IT services in-house after examining outsourcing options (Lacity and Hirschheim 1995; Hirschheim and Lacity 2000). We conducted 14 in-depth U.S. client case studies on organizations that examined but rejected outsourcing. We wanted to know: Did the internal IT organization change as a consequence of the insourcing decision? Among the 14 cases, two companies backsourced IT services after terminating outsourcing contracts. In both backsourcing cases, IT service levels improved, but IT costs rose in one backsourcing case and IT costs remained the same in the other backsourcing case. In three client organizations, no changes in IT performance resulted from the insourcing decision. However, in nine client companies, IT performance significantly improved. IT costs were reduced between 20% and 54% by replicating provider practices such as centralization, standardization, and rationalization. Business users accepted the drastic changes implemented to achieve such cost savings because they realized that if the internal IT organization did not implement these changes, an outsourcing provider would. The message was: the devil you know is better than the devil you do not know.

In contrast to the small academic literature on insourcing outcomes, hundreds of academic studies have examined outsourcing outcomes. Most of this research is based on large-sample surveys of outsourcing clients or in-depth case studies at client sites. Across these studies, researchers have used many different types of measures to examine the outcomes of outsourcing. The most frequently used measures include outcomes that capture a client's general perceptions of the success or level of satisfaction with outsourcing in general or with offshore outsourcing in particular, perceptions of the quality of relationships, and the effects of outsourcing on a client organization's business performance, such as improvements in stock price performance, return on assets, expenses, or profits after outsourcing (Lacity and Willcocks 2012b). By aggregating findings from both qualitative and quantitative studies in Lacity et al. (2010a), we reported the following: *IT outsourcing decisions resulted in positive outcomes in 63% of the findings, negative outcomes in 22% of the findings, and no changes in performance as a consequence of outsourcing were reported in 15% of the findings*. Many people might consider this statistic quite disappointing because only 63% of ITO engagements were considered positive by clients. The good news is that scholars have studied the determinants of ITO outcomes. We thus have a strong understanding of the practices that differentiate positive from negative outcomes.

60.5 Determinants of ITO Outcomes

Based on our review of the empirical ITO research, we extracted what we call robust practices, practices that have been academically tested and proven to be effective. These practices are grouped into five categories: transaction attributes, contractual governance, relational governance, client-retained capabilities, and provider capabilities (see Figure 60.1).

TABLE 60.6 Transaction Attributes Affecting Outsourcing Outcomes

Transaction Attributes	Description
Uncertainty	The degree of unpredictability or volatility of future states as it relates to the definition of IT requirements, emerging technologies, and/or environmental factors (e.g., Williamson 1991b; Poppo and Zenger 2002; Aubert et al. 2004)
Measurement difficulty	The degree of difficulty in measuring performance of exchange partners in circumstances of joint effort, soft outcomes, and/or ambiguous links between effort and performance (e.g., Eisenhardt 1989)

60.5.1 Transaction Attributes

ITO researchers have studied 17 transaction attributes to determine whether outsourcing certain types of transactions was more or less likely to result in positive outcomes (Lacity et al. 2011a). For example, ITO researchers have asked, "Are large or small transactions likely to result in positive outcomes?" and "How does task complexity affect outcomes?" Overall, only two transaction attributes were repeatedly tested and found to affect ITO outcomes: uncertainty and measurement difficulty. Both of these transaction attributes are negatively and significantly related to ITO outcomes. These two transaction attributes are derived from Transaction Cost Economics (Coase 1937; Williamson 1975, 1991a,b). Of the 15 times uncertainty was studied, 12 times (80%) researchers found that uncertainty adversely affected ITO outcomes (e.g., Barthélemy 2001). Measurement difficulty was examined seven times and was found to adversely affect ITO outcomes six times (86%) (e.g., Poppo and Zenger 2002; Table 60.6).

60.5.2 Contractual Governance

Contractual governance is the formal, written rules that govern client–provider relationships. In scholarly works we reviewed, contractual governance was operationalized most frequently as degree of contract detail (e.g., the types of clauses, number of service-level agreements), contract duration, contract value, and contract type (e.g., fixed price, time, and materials). *Substantial evidence finds that* (1) *more detailed contracts*, (2) *shorter-term contracts, and* (3) *higher-dollar-valued contracts are significantly associated with positive outsourcing outcomes* (Lacity et al. 2010a,b). Detailed contracts that defined the scope of services, prices, service levels, and responsibilities of both parties and prescribed how parties would adapt to changes in character, volume, or market best practices had better outsourcing outcomes than contracts with fewer details. Shorter-term ITO contracts in the 3–5 year range experienced successful ITO outcomes more frequently than contracts with greater than 5 year duration. Higher-valued contracts perform better than lesser-valued contracts because the transaction costs associated with outsourcing are spread over a greater volume of work.

Contract type is a term denoting different forms of contracts used in outsourcing. Examples from the ITO literature include customized contracts, fixed-price contracts, time and materials contracts, fee-for-service contracts, and partnership-based contracts. ITO researchers used different categories of contracts across studies. For example, Lacity and Willcocks (1998) used three categories and found that clients who signed fee-for-service contracts had higher rates of success than clients who signed strategic alliances or loose contracts. In Lacity and Rottman (2008), we found that different contracts incent providers differently. In the offshore context, clients found that time and materials contracts produced better work, but at considerable expense to the client. Providers were not pressured to take shortcuts in order to protect their profit margins as they were with fixed-price deals. Also, some providers placed new employees on client accounts because the client subsidizes the employee's learning curve with time and materials contracts. Ironically, provider employees who are unproductive take more hours to complete tasks, which generates greater provider revenues. In Gopal et al. (2003), contract type was a categorical variable (either fixed price or time and materials) and the authors found that requirements uncertainty

TABLE 60.7 Contractual Governance

Contractual Governance	Description
Contract detail	The number or degree of detailed clauses in the outsourcing contract, such as clauses that specify prices, service levels, benchmarking, warranties, and penalties for nonperformance (e.g., Pinnington and Woolcock 1995; Poppo and Zenger 2002)
Contract duration	The duration of the contract in terms of time (e.g., Lacity and Willcocks 1998)
Contract value	The size of the outsourcing contract usually measured as the total value of the contract in monetary terms (e.g., Oh et al. 2006; Rottman and Lacity 2008)
Contract type	A term denoting different forms of contracts used in outsourcing. Examples include customized, fixed-price, time and materials, fee-for-service, and partnership-based contracts (e.g., McFarlan and Nolan 1995; Poppo and Zenger 2002; Ross and Beath 2006)

was associated with time and materials contracts. They also found that supplier profits were higher for time and materials contracts than for fixed-price contracts (Table 60.7).

60.5.3 Relational Governance

Relational governance comprises the informal rules that manage client–provider relationships. In scholarly works we reviewed, relational governance was operationalized most frequently as effective knowledge sharing, communication, trust, and viewing the provider as a partner (see Table 60.8). In 94% of the findings, the research showed that higher levels of relational governance were associated with higher levels of outsourcing success (Lacity et al. 2010a,b). In some ways, the findings are trivial. Few people would argue that withholding knowledge, closed communications, or distrusting providers would lead to better outsourcing relationships. A more interesting research finding is that contractual governance and relational governance serve as complements, in that both need to be strong to produce positive outsourcing outcomes (Saunders et al. 1997; Sabherwal 1999; Poppo and Zenger 2002; Wűllenweber et al. 2008; Goo et al. 2009). In general, contractual governance and relational governance are not substitutes in that a poorly crafted contract cannot be overcome with friendly, communicative, and trusting account managers. Poor contracts, we have found, can make for poor relationships (Lacity et al. 2010a,b; Lacity and Willcocks 2012a).

60.5.4 Client-Retained Capabilities

Research has found that clients must learn to manage differently after outsourcing in order to achieve expected benefits (see Table 60.9). Clients must become good at managing providers by shifting their capabilities from managing resources and processes to managing inputs and outputs. This is not an easy transition for many clients. The supplier management capability was often found to be lacking in client organizations and seen as a major reason to explain negative outsourcing outcomes. Clients also need a strong contract negotiation capability, which is frequently supplemented with the aid of advisory firms.

TABLE 60.8 Relational Governance

Contractual Governance	Description
Effective knowledge sharing	The degree to which clients and suppliers are successful in sharing and transferring knowledge (e.g., Lee 2001; Murray et al. 2009)
Communication	The degree to which parties are willing to openly discuss their expectations, directions for the future, their capabilities, and/or their strengths and weaknesses (e.g., Klepper 1995)
Trust	The confidence in the other party's benevolence (e.g., Dibbern et al. 2008)
Partnership view	A client organization's consideration of suppliers as trusted partners rather than as opportunistic vendors (e.g., Saunders et al. 1997; Kishore et al. 2003)

TABLE 60.9 Client-Retained Capabilities

Capability	Description
Supplier management capability	The extent to which a client organization is able to effectively manage outsourcing providers (e.g., Feeny and Willcocks 1998; Willcocks et al. 2007)
Contract negotiation capability	The extent to which a client organization is able to effectively bid, select, and negotiate effective contracts with providers (e.g., Feeny and Willcocks 1998)
IS technical/methodological capability	A client organization's level of maturity in terms of technical- or process-related standards including the Capability Maturity Model (CMM), Capability Maturity Model Integrated (CMMI), and the Information Technology Infrastructure Library (ITIL) and best practices such as component reuse (e.g., Davenport 2005; Rottman and Lacity 2006; Kotlarsky et al. 2007)
Cultural distance management capability	The extent to which client and provider organizations understand, accept, and adapt to cultural differences (e.g., Winkler et al. 2008)
Risk management capability	A client organization's practice of identifying, rating, and mitigating potential risks associated with outsourcing (e.g., Smith and McKeen 2004)

Technical and methodological capability is another important client-retained capability. Technical and methodological capability is an operational capability needed by both parties in order to coordinate work effectively. Clients must learn to understand, accept, and adapt to cultural differences between themselves and their providers (cultural distance management capability). A client also needs to be able to identify, rate, and mitigate potential risks associated with outsourcing (risk management capability). Other client capabilities have also been identified as affecting outsourcing decisions and outcomes: absorptive capacity, client outsourcing readiness, change management capability, human resource management capability, and transition management capability (Lacity et al. 2010a). Clearly outsourcing is not about abdicating management responsibility, but about managing differently.

60.5.5 Provider Capabilities

Which provider capabilities contribute to positive outsourcing outcomes? The three most frequently studied and most important provider firm capabilities were human resource management capability, technical and methodological capabilities, and domain understanding (see Table 60.10). A provider's ability to identify, acquire, develop, and deploy human resources to achieve both provider's and client's organizational objectives was found to positively and significantly affect client outcomes 95% of the time it was examined. Clients often engage providers because of their superior human resources in terms of both number and quality of staff. The provider's technical and methodological capability was

TABLE 60.10 Provider Capabilities

Capability	Description
IS human resource management capability	A provider organization's ability to identify, acquire, develop, and deploy human resources to achieve both provider's and client's organizational objectives (e.g., Levina and Ross 2003)
IS technical/methodological capability	A provider organization's level of maturity in terms of technical- or process-related standards including the CMM, CMMI, and ITIL and best practices such as component reuse (e.g., Levina and Ross 2003)
Domain understanding	The extent to which a provider has prior experience and/or understanding of the client organization's business and technical contexts, processes, practices, and requirements (e.g., Clark et al. 1995; Gopal et al. 2002)

the second most frequently studied capability, and it was found to affect outcomes positively. Domain understanding is the extent to which a provider has prior experience and/or understanding of the client organization's business and technical contexts, processes, practices, and requirements. Other provider capabilities were also found to be important: client management capability, managing client expectations, supplier employee performance, risk management capability, security, privacy and confidentiality capability, supplier's core competencies, absorptive capacity, environmental capability, and corporate social responsibility capability (Lacity et al. 2010a). Providers are unlikely to excel in all of these areas, but better capabilities lead to better outcomes.

60.6 Research Opportunities

Despite the maturity of IT sourcing research, academics still have opportunities to advance the theory and practice of IT sourcing. In Lacity et al. (2010a), we identified nine gaps in IT sourcing knowledge. We called for more studies on (1) strategic sourcing decisions, (2) strategic sourcing outcomes, (3) dynamic interactions between client and provider firm capabilities, (4) environmental influences on sourcing decisions and outcomes, (5) configurational and portfolio approaches, (6) alternative locations, (7) emerging trends and models like cloud computing, (8) informing reference discipline theories, and (9) developing endogenous ITO theories. Pertaining to the last two gaps, ITO studies are highly informed by reference theory disciplines, particularly theories from economics (e.g., transaction cost economics, agency theory), management (e.g., resource base view, institutionalism), and sociology (e.g., social exchange theory, social capital theory). Many of these theories fail to adequately explain ITO phenomena—a debate that has been thoroughly discussed in a number of sources, including Lacity and Willcocks (2009), Lacity et al. (2011b), and Karimi Alaghehband et al. (2011).

ITO researchers have found so many anomalies that are counter to TCE logic in the ITO context, that we believe it is more fruitful to develop a theory specific to ITO. We analyzed the TCE anomalies in the ITO context and categorized them by research methods explanations, boundary conditions explanations, TCE assumption violations, and alternative theory explanations. With *research method explanations*, ITO researchers do not assume that their data provide evidence counter to TCE logic but instead attribute lack of empirical support of TCE to measurement problems, or to some TCE effects overpowering other TCE effects. *Boundary condition explanations* attribute lack of empirical support of TCE to the distinctive context of ITO, such as the distinctive nature of IT, the distinctive research setting (e.g., such as public sector IT), or the distinctive attributes of the data collected. *TCE assumption violation explanations* argue that TCE's explicit or implicit assumptions are unsupported. TCE is based on two explicit behavioral assumptions: bounded rationality and opportunism (Williamson 1991a) and ITO authors found evidence that TCE behavioral assumptions were violated in ITO context (Lacity and Willcocks 1995; Tiwana and Bush 2007; Dibbern et al. 2008). Finally, *alternate theory explanations* suggest that other theories are more powerful in explaining ITO. Based on so many anomalies in the ITO empirical tests of TCE, we argued that we are asking too much of TCE—the ITO phenomenon is more complex than can be accommodated by one decision-making theory.

In Lacity et al. (2011b), we further developed the idea of an endogenous ITO theory by arguing that such a theory should be based on three assumptions. (1) We assume that stakeholder alignment must be actively and aggressively designed anew in the face of ITO. (2) We assume that managerial practices such as standardization, centralization, and tight controls contribute more to IT costs than economies of scale. (3) We assume that history matters; merely using the transaction as the unit of analysis overlooks the broader historical context that sheds significant understanding on ITO decisions and outcomes. We found that an organization's prior history with delivering IT, with prior ITO experiences, and client capabilities are all vital to understanding the ITO decisions an organization makes today. Thus, there are many opportunities to advance the theory of IT sourcing.

Researchers also have opportunities to contribute to practice. We describe three enduring practitioner ITO challenges: (1) adaptability, (2) measurement, and (3) innovation. Each of these areas needs rigorous research.

60.6.1 Challenge 1: Adaptability

Adapting to change is a pervasive outsourcing challenge. Many participants from our recent research continue to comment that their contracts were out of date even before the ink was dry (Lacity and Willcocks 2012b). Change comes from many sources:

- The client's business process and IT requirements change.
- The client's volume of services fluctuates unpredictably.
- The market price changes radically as labor costs rise, technology costs decline, or market prices alter with changes in demand, currency value, or political stability.
- The market's best-in-breed service performance improves.
- The political support for outsourcing within client organizations wane with senior executive turnover.

Partners try to design flexible ITO contracts to adapt to such changes, particularly during a long-term relationship. Standard in contracts are clauses for volume fluctuations for when additional resource charges (ARCs) or reduced resource charges (ROOKs) apply, force majeure clauses, change of character clauses, and external benchmarking to reset prices or service levels. To one extent, these contract clauses are effective. As noted earlier, greater contract detail was associated with better outsourcing outcomes in the empirical ITO review. In our case study research, we continue to hear laments that big changes cause severe consequences to the economic viability of the disadvantaged partner. In practice, significant change harms either the client or provider, which can result in a dispute (Lacity and Willcocks 2012b).

60.6.2 Challenge 2: Measurement

The maxim "you can't manage what you can't measure" has been long embraced by ITO practitioners. In contracts, there is no shortage of measures, but the enduring challenge is to measure the right things that matter to clients and to incent providers to deliver what matters most to the client. In our research, we find that providers—quite understandably—will only agree to measure processes in which they have complete control. These measures, however, are typically a small piece of the end-to-end process. Consider, for example, the process of IT user support. Clients want providers to identify root causes and propose fixes, yet the measures may incent the providers to replicate the same easy fix for each user that calls rather than fix it once for the entire user community. In our recent BPO research, high performing relationships measure end-to-end processes. Parties first diagnose the root causes for service issues, propose solutions to improve the end-to-end process, and only then determine what it means for the commercial relationship.

60.6.3 Challenge 3: Innovation

Even satisfied ITO clients invariably ask, "Yes, the suppliers are delivering on the contract, but where is the innovation?" At the beginning of the deal, the usual sticking point is who will pay for innovation. Sometimes, clients establish an innovation fund against which approved client/provider proposals can draw. However, if incarcerated inside a traditional cost-service-focused contract, such an initiative rarely has the size or priority to make inroads. Providers are reluctant to spend time and expert resources on an ancillary part of the contract, especially when clients themselves do not take the positive action required from them to work together with the provider to achieve the more business impactful innovations beyond minor IT operational changes (Lacity and Willcocks 2011).

60.7 Conclusion

We have consistent evidence as to what motivates IT sourcing decisions. IT executives want to reduce costs, to focus on core capabilities, and to inject IT organizations with provider resources such as skills, expertise, and superior technology to improve client IT performance. IT executives are more likely to insource IT activities that have high levels of uncertainty, criticality, business risks, and transaction costs. On the determinants of ITO outcomes, overall we know that both contractual and relational governance are important, that both clients and providers need strong complementary capabilities to make relationships successful, and that certain types of transactions and decisions affect ITO outcomes.

Outsourcing has become an almost routine part of management, but 20 years of research establishes the common denominator that, for management and operational staff, outsourcing requires detailed oversight. Outsourcing itself is not a panacea to a client's IT challenges, but represents a different way of managing IT services. Much depends on experiential learning and sheer hard work by clients and providers alike on a daily basis. Our own work on management practice suggests that back office executives must climb a significant learning curve and build key in-house capabilities in order to successfully exploit outsourcing opportunities. They need to accept that outsourcing is not about giving up management but managing in a different way. We also find providers continually having to readdress their capabilities, their market offerings, and competitive forces. In the face of these difficulties, outsourcing will remain a fascinating and growing area for research for many years to come. It also provides a notable area where academic researchers and the distinctive qualities they bring to bear can continue to provide rich insight and guidelines in an emerging, expanding, but still much muddied field of organizational operation (Lacity and Willcocks 2012b).

IS/IT Project Management: The Quest for Flexibility and Agility

Laurie J. Kirsch
University of Pittsburgh

Sandra A. Slaughter
Georgia Institute of Technology

61.1 Introduction

Providing technological capabilities to an organization in support of ongoing or new business initiatives is a core responsibility of the information systems (IS) function. IS/ information technology (IT) project management is therefore a key capability since the delivery of technological capabilities—from understanding user requirements to acquiring a technological solution to implementing the system—often falls to project teams led by an IS/IT project manager. IS/IT project management involves understanding the requirements of a project, developing a plan to deliver a product or service, and implementing the plan. IS/IT project managers are tasked with delivering a particular technological capability (e.g., an information system) to satisfy scope and quality requirements within specific time, budget, and resource constraints.

The context of managing IS/IT projects has changed dramatically over time. When computers were first introduced into organizations, it was common to develop custom information systems in-house. For example, in the United States, the first administrative information system was a payroll system developed by General Electric. In 1954, General Electric purchased a Univac I computer to use in its new Major Appliance Division plant in Louisville, Kentucky. GE Corporate Accounting Services took primary responsibility for managing this project, which involved designing and programming the first payroll information system to be used initially by the Washer and Dryer Department.* As part of its plan to automate its production facilities and make Louisville a showcase location, GE decided to use the computer not only to process payrolls and other accounting applications but also for manufacturing control and planning.

* See http://www.softwarehistory.org for more information about the history of the software industry and Burton Grad's first person description of his experiences in programming the first commercial information system at GE (http://www.softwarehistory.org/pdf/x-1stCommCompAppGE.pdf).

From the 1950s well into the 1970s and beyond, sourcing options for information systems were few, and most systems were built by internal IS staff. As the GE example illustrates, information systems were typically designed to meet specific needs, usually for one particular functional area and typically focused on an operational aspect of the business. If a development methodology was used, it was most likely the waterfall (Systems Development Life Cycle) approach. The waterfall process, based on functional decomposition, consumed considerable time and effort and produced a wealth of documentation, including design documents, sign-offs, and responsibility charts, all intended to hold IS professionals accountable for producing a well-designed, well-constructed, and maintainable system. Consistent with the waterfall approach to development, most project managers and developers commonly assumed that information requirements were known, could be elicited, and would be stable. Thus, the waterfall process provided IS/IT project managers with a template for planning and execution, with its series of steps performed in a sequential manner.

The context of computing started to change rapidly, however, beginning in the 1980s. The prevalence of the personal computer and end-user computing, followed by the rise of the Internet and web-based computing, provided firms with many more technical capabilities and options. The business environment was also changing. Firms found themselves in an increasingly global, dynamic, and, in some industries, a highly regulated environment. Global competition, customers, and suppliers became the norm rather than the exception for most firms. Successful firms learned to adapt and evolve in order to respond to ever-changing consumer demands and competitor actions in the marketplace, as well as shifting resource availability and costs along the global supply chain.

The changes in the business environment converged with the rapidly changing technology such that more and more firms today expect information systems to allow for rapid response to both anticipated and unanticipated change (Lee and Xia 2005, 2010; Lyytinen and Rose 2006; Maruping et al. 2009). The complexity, volatility, and uncertainty inherent in the business environment demand *flexibility* and *agility* in the design and delivery of information systems and, correspondingly, the management of IS/IT projects. Flexibility is defined as the ability to adapt and change (Elfatatry 2007, p. 36). Agility, in this context, refers to "the ability to sense and respond swiftly to technical changes and new business opportunities" (Lyytinen and Rose 2006, p. 183).

Satisfying a firm's need for flexibility and agility in its computing environment encompasses various aspects related to information systems acquisition and delivery. Not only must information systems themselves deliver flexibility, but the development methodologies and project management approaches must privilege adaptability and nimble responses to change. Further, firms desire flexibility and agility when they are looking to acquire a new system, and no longer view internal custom development as their only option for sourcing an information system. The waterfall approach as a template for project management becomes less relevant in an environment characterized by change and uncertainty.

This chapter explores IS/IT project management in contemporary firms. We start by considering the underlying principles of IS/IT project management. This includes an overview of modern project management as well as a detailed examination of the context of IS/IT projects, with a particular focus on flexibility and agility. Next, we discuss approaches for managing highly uncertain and volatile projects as IS project managers and teams strive to deliver flexibility and agility. We then explore research opportunities in IS/IT project management. We end this chapter by offering a few concluding remarks.

61.2 Underlying Principles of IS/IT Project Management

Though individuals have been managing projects for centuries, project management, as a profession, is relatively young; it was in 1969 that the Project Management Institute (PMI), a nonprofit association, was established with a mission to foster the profession of project management. By 1990, there were 7500 members of the PMI; today, there are over 600,000 members in more than 185 countries.* The PMI

* See http://www.pmi.org for more details about the PMI.

offers various certifications to practicing project managers, including the Certified Associate in Project Management (CAPM) and the Professional Project Manager (PMP) certifications.

As part of its mission, the PMI has identified and codified the project management body of knowledge (PMBOK), the ten knowledge areas that all project managers must master to achieve CAPM or PMP certification. The knowledge areas are scope, time, cost, quality, human resources, communication, risk, procurement, stakeholder, and integration management. Project managers make decisions and take actions related to each knowledge area in an overlapping fashion across project management "process groups": project initiation, planning, execution, monitoring and controlling, and project closing. The PMBOK maps activities associated with each knowledge area into the process groups.

The efforts of the PMI have had a profound impact on professionalizing project management in IS/IT as well as in other disciplines. However, the practice of IS/IT project management has also been greatly influenced by the methodologies used to develop information systems. Methodologies provide templates for managing projects since they articulate activities and processes associated with developing and delivering information systems. As methodologies have evolved, so has IS/IT project management. Therefore, we next examine the information systems development (ISD) process and highlight the relationship between ISD approaches and IS/IT project management.

ISD is the process by which computer software is specified, written, tested, and implemented. The waterfall process, a conventional approach to ISD, involves planning, analysis, design, coding, testing, implementation, and maintenance (George 1999). However, for today's firms, the types of systems being developed, as well as the way in which they are developed, have evolved considerably since the 1950s. Initially, firms generally built single-purpose, stand-alone systems for a particular department or functional unit. Today, we are more likely to find one of two scenarios. The first is the development of smaller systems, often tightly integrated with others. One example is adding a web-based front end to an existing legacy system to improve its usability. The second scenario is the development of very large, complex systems that are often global or inter-organizational in scope. In contemporary firms, the choice of methodology is also changing. The conventional waterfall approach to development is just one of many that may be used; alternatives include the spiral model and agile methods. Over time, project management has also evolved so that today it tends to be more formalized and less ad hoc. Table 61.1 compares the characteristics of traditional systems development and project management with emerging trends found in contemporary firms.

TABLE 61.1 Comparing Traditional and Contemporary Systems Development and Project Management

	Traditional Practices	Contemporary and Emerging Trends
Requirements	Stable and predictable	Emergent and uncertain
System characteristics	Single purpose and stand alone	Smaller and tightly integrated or larger and spanning units
Design philosophy	Design a system for long-term use	Design a system for adaptability
Common development method	SDLC or waterfall	Spiral or agile methods
Methodology approach	Functional decomposition	Component-based design
Methodology assumptions	Predictability and longevity	Uncertainty and flexibility
Methodology principles	Heavyweight	Lightweight
Project management approaches	Ad hoc, individual processes	More formalized approaches
Role of user	Minimal or token user participation	Partner in deployment of IS
Project teams	Colocated	Geographically distributed
Managing project teams	Simplistic understanding and use of control and coordination mechanisms	More nuanced understanding and use of control and coordination mechanisms

In today's quest for flexible and agile systems, three aspects of managing IS/IT projects deserve particular attention: requirements determination, design considerations, and sourcing options. Successfully determining requirements is a crucial step in an IS/IT project, but it is notoriously difficult, particularly when requirements are ambiguous or fluctuating. In addition, developing systems that are adaptable and flexible can heighten the challenge of determining requirements. Similarly, the principles underlying the design of a technical solution have implications for the nature of the solution itself. Whether a system is adaptable over time is, in part, a result of how the system was initially designed. Finally, the way in which a system is sourced—whether it is custom developed or acquired—has implications in terms of flexibility and agility. The method chosen to develop a technical solution varies in its ability to accommodate change: some methods are constraining while others are better suited to handle changes and produce systems that are flexible and agile. Moreover, increasingly organizations are turning away from custom development and considering alternate sourcing options. Accordingly, IS/IT project managers need to understand the advantages and disadvantages of a variety of sourcing options in order to choose the approach that best fits the needs of the system and the organization. In the following sections, we explore requirements determination, design considerations, and sourcing options in some depth, with a focus on flexibility and agility.

61.2.1 Requirements Definition

Research over the last 25 years has repeatedly highlighted the many challenges associated with requirements determination, including ambiguous requirements, communication obstacles, difficulty in reaching consensus on global needs, and the thin spread of domain knowledge across stakeholders (Alvarez 2002; Curtis et al. 1988; Urquhart 2001; Walz et al. 1993). The challenges are compounded in contemporary firms where the business needs are highly volatile and requirements change as systems are developed in response to emerging business needs or increased understanding of a complex business environment (Kirsch and Haney 2006; Maruping et al. 2009). Moreover, needs and requirements may be largely unknown at the start of a project, and may instead emerge as the project unfolds. Dynamic and emergent requirements represent a considerable departure from prior years, when requirements were regarded as specifiable and stable.

IS/IT project managers may increasingly be called upon to develop systems with emergent requirements. For example, there is growing interest and investment in large-scale, multiparty information systems that span disciplines and institutions and are geared toward supporting collaboration among many stakeholders (Berman 2008; Levina 2005). An example of this type of project is a cyberinfrastructure project (or "cyber project"). *Cyberinfrastructure* refers to integrated information technologies (i.e., hardware, software, digital sensors, middleware, networks, and data components) that support scientific research activities (Berman 2008; Bietz et al. 2010; Edwards et al. 2009). A specific objective of cyberinfrastructure is to foster innovative research and discovery through the use of technologies that support distributed collaborative work among geographically dispersed researchers (de la Flor et al. 2010; Ribes and Lee 2010). An example of cyberinfrastructure is the George E. Brown, Jr. Network for Earthquake Engineering Simulation (or NEES), which was created to better understand earthquakes, their causes, and effects.* NEES provides researchers, scholars, and industry access to state-of-the-art technologies and resources, augmenting their ability to study complex questions about earthquakes, to predict when earthquakes will occur, and to provide guidance to governments and emergency responders.

A "cyber project" refers to the information technology (IT) development activities that design, build, integrate, test, and implement a specific cyberinfrastructure. Cyber projects tend to be large and complex: they involve stakeholders from industry, academia, and government with varying goals and requirements, and they often cost millions of dollars and require years to develop (Finholt and Birnholz 2006). Because cyberinfrastructure is meant to promote experimentation and discovery, the requirements are emergent and unpredictable. In fact, the project outcomes are often unknowable and

* For more information, see http://www.nees.org

unpredictable: as a cyber project unfolds over time, the vision and goals associated with the project will themselves evolve in response to the ongoing experimentation and discovery.

Though cyber projects may be an extreme example in terms of fluctuating and emergent requirements, they nevertheless are illustrative of the challenges associated with managing volatile requirements. IS/IT project managers must recognize volatility and learn to adapt the way in which these projects are managed (Maruping et al. 2009). With fluctuating requirements, there is increased need for IS/IT project managers to promote ongoing mutual learning between providers of solutions and customers. Some methods are designed to accommodate changing requirements. Prototyping, spiral development methodologies, and rapid application development (RAD) assume that requirements are difficult to elicit and encourage iteration between developer and customer. For example, consider a cyber project called Global Environment for Network Innovation (GENI). The goals of GENI are to develop a virtual laboratory at the frontiers of network science and engineering for exploring future internets at scale (see http://www.geni.net). Given these goals, the project faces a considerable amount of requirements uncertainty. To address this uncertainty, the project is managed using spiral development. Each spiral lasts 1 year and consists of projects that develop different networking technologies. After each spiral, the project manager evaluates the success and failure of the technologies and decides on the technology goals for the next spiral. Spiral development affords the opportunity to explore cutting-edge technologies and provides flexibility to discontinue less promising technologies while affording the ability to explore new technology opportunities. From a project management perspective, however, the spiral approach—particularly as it is implemented in the GENI cyber project—introduces considerable complexity into the management process as there are multiple moving parts to coordinate and oversee.

Newer agile methods also generally recognize the need for intensive user–developer interaction. Using eXtreme programming (XP), for example, customers write brief “user stories” explaining what a system needs to do, and developers estimate the time needed to implement that functionality. Later in the process, the developer receives more details from the customer in order to implement the story.*

In the context of emergent requirements, it is also important for IS/IT project managers to recognize that customers will not be able to fully specify requirements at the start of a project (Curtis et al. 1988; Maruping et al. 2009; Urquhart 2001). A number of empirical studies have highlighted the role of learning and intense analyst–user interactions especially in the context of poorly understood requirements and ill-structured problems (Alvarez 2002; Boland 1978; Kirsch and Haney 2006; Lyytinen and Robey 1999).

61.2.2 Design Approaches

In the past, systems were built for long-term use. The need for flexible, adaptable systems was not paramount as business environments were relatively stable. Contemporary firms, though, face a completely different environment, one in which competitors, products, and regulations are changing quickly and often in unpredictable ways. IS/IT project managers must understand this changing environment and adapt accordingly.

One response to the need for flexibility and agility is a modular approach to designing and implementing systems, based on a specific plan or architecture. An architecture incorporates a high-level understanding of the requirements, the solution, the modules, subsystems, and interface, as well as a broad plan for deployment (Goodhue et al. 1992; McBride 2007). When systems are designed without an architecture, they often evolve haphazardly, are difficult to change, and ultimately fail to meet the needs of the business (McBride 2007). In contrast, when an architecture is in place and followed, systems are designed for change because they are built in modules using standardized parts, which facilitates future adaptations. Thus, an architecture and modular design provide firms with flexibility and agility to deal with highly dynamic requirements.

* See http://www.extremeprogramming.org for additional information.

Recent studies have provided insights into the role of modular architectures in system adaptability. In a qualitative study, Collins and Kirsch (1999) observed the use of modular, incremental design and deployment in response to a dynamic and turbulent business environment. For example, in one firm, a complex global system was designed in relatively small increments (typically 6 months or less project duration) for geographically dispersed business units to implement and adapt to local requirements as needed. Moreover, researchers have begun to document the positive impacts of modular design. For example, in a field study of system enhancement activity over a 20 year time period, Barry, Kemerer, and Slaughter (2006) found that greater use of a standard architecture in a system localizes changes to specific components. The findings demonstrate that a standard architecture increases the design integrity and stability of the system while at the same time accommodating change.

Model-driven architecture (MDA) is a relatively recent software design approach that can be adopted for the development of information systems. MDA provides guidelines for specifications, expressed as models, and was launched by the Object Management Group (OMG, http://www.omg.org/mda). Itinvolves producing software code from abstract modeling diagrams (Frankel 2003). MDA can introduce flexibility and agility in the software development process by separating design from architecture. This separation allows the designer to address the functional (use case) requirements while the architecture provides the infrastructure through which nonfunctional requirements like scalability, reliability, and performance are addressed. Separating design from architecture allows developers to take advantage of the latest techniques and technologies for each, while providing an architecture that is robust to changes.

Another design approach that affords considerable flexibility and agility in software projects is component-based development (CBD). An individual software component is a package, service, or module that encapsulates a set of related functions (or data). CBD is a reuse-based approach to defining, implementing, and composing loosely coupled independent components into systems (Heineman and Councill 2001). This approach allows the ability to "plug and play" components into software architectures, and components play a central role in service-oriented architectures (SOA). A recent field study of CBD by Subramanyam, Ramasubbu, and Krishnan (2012) found that CBD approaches are associated with what the authors call "efficient flexibility" in the development of business information systems.

61.2.3 Sourcing Options

Achieving flexibility and agility goes beyond requirements determination and design considerations. It is also important that IS/IT project managers consider sourcing options. We first consider in-house development methodologies and then turn our attention to a variety of external sourcing options.

Custom in-house development is the traditional approach to acquiring an information system in which an organization's IT staff develop and install a system designed to meet the unique needs of the organization. Custom in-house ISD allows for meeting highly specialized requirements, facilitates changes to firms' business processes, and helps to build up personnel skills in the organization. It also provides firms with a certain kind of flexibility—that is, the flexibility to creatively solve business problems, and to develop a solution that fits the particular nuances of a firm's business environment. Custom in-house development enables firms to continually adapt and enhance their information systems to meet unique needs.

However, custom in-house development can also be constraining in that it generally takes a long time to develop a software solution internally. Moreover, custom in-house ISD can tax an organization's resources and may incur significant risk. It is not uncommon for ISD projects to be over budget, run over schedule, and not deliver the required functionality (Barki et al. 2001; Keil 1995). Some projects are abandoned, without developing any useful parts of a system. One recent example is the Virtual Case File (VCF). The VCF project was supposed to automate the FBI's paper-based work environment and allow agents and intelligence analysts to share investigative information. After years of effort, the VCF's contractor, Science Applications International Corp. (SAIC), in San Diego, delivered 700,000 lines

of code; however, the software was largely unusable, and the FBI had to scrap the entire $170 million project and start over from scratch (Goldstein 2005).

Because the conventional waterfall approach is often seen as too cumbersome and time-consuming to be effective when flexibility, speed, and agility are paramount (Lyytinen and Rose 2006; Slaughter et al. 2006), firms are increasingly turning to agile methods, a set of practices intended to minimize unnecessary bureaucracy and maximize adaptability and responsiveness. The Agile Manifesto, composed by a group of "independent thinkers about software development" who advocate lightweight, agile methods for development, highlights four distinct value propositions*:

1. Individuals and interactions over processes and tools
2. Working software over comprehensive documentation
3. Customer collaboration over contract negotiation
4. Responding to change over following a plan

While XP and Scrum are the most widely known and used agile methods, there are a number of others, including the Rational Unified Process (RUP) and Dynamic Systems Development Method (DSDM) (Boehm and Turner 2003).†

Despite the advances in development methodologies, custom design and development often are risky, lengthy, and prone to failure (Barki et al. 2001). Thus, organizations often turn to other sourcing strategies. Today, there are many viable alternatives for acquiring IS that a firm and its IS/IT management can consider. These include packaged software, outsourcing, and offshoring. Each is explored as follows.

Packaged software is code written by a vendor for purchase by organizations and use "off the shelf." The package provides common functionality and may allow for customization of certain features. Packaged software is available in a wide variety of systems, sizes, and prices. For example, Enterprise Resource Planning (ERP) systems are very large software packages that enable organizations to integrate business processes across functional areas. ERP packages can be contrasted with smaller, more special purpose software packages such as for payroll and office productivity. Compared with custom development, software packages offer numerous advantages. First and foremost, the software is already written and functioning, and this may save time and reduce the risk of unusable code. The software may be more thoroughly tested and proven as it has been used in many organizations. On the other hand, the organization must pay for and accept the functionality provided, even if not all of the functionality is used. It can be very costly to "customize" a package, even if the vendor allows it (Davis 1988). A larger issue is that the organization may have to significantly change how it does business in order to use the software (Elbanna 2010). Research on implementing software packages, such as ERP systems, suggests that the greater the "misfits" between the package and the organization's needs, the greater the cost and effort of implementation and the higher the risk of failure (Soh et al. 2000). In terms of flexibility and agility, packaged software provides agility in acquisition, as the time to acquire the software is short (compared to in-house custom development), although implementation can still be complex and lengthy. However, the flexibility to change the software is less than for in-house developed systems as the organization must negotiate with the vendor to make the changes.

Outsourcing involves hiring an external vendor, contractor, or service provider to create or support an information system. Information systems outsourcing has been a viable sourcing strategy since the early days of computing. Organizations can outsource their entire IT function (total outsourcing) or can outsource some systems or processes (selective outsourcing). An increasing percentage of organizations are currently outsourcing or considering it.

---

* See http://www.agilemanifesto.org for additional information.

† The degree of agility embodied in any method can vary. See, for example, http://www.ibm.com/developerworks/rational/library/edge/08/feb08/lines_barnes_holmes_ambler for a discussion of how RUP can support an agile approach to development.

Outsourcing offers numerous advantages as a sourcing strategy. By outsourcing, organizations can tap into the potentially broader and deeper IT experience and skill base of a vendor (Lacity and Willcocks 1998). The vendor may be more cost-efficient in providing IT services due to economies of scale in servicing multiple firms (Levina and Ross 2003). Outsourcing also can afford an organization greater agility (Lacity et al. 1995); for example, in the early 1990s Xerox outsourced software maintenance so that Xerox's IT staff could focus on new systems development. However, there are some important disadvantages of outsourcing (for a review, see Lacity et al. 2009). Generally, by hiring an external party to develop the information system, the client can lose control over the development process as well as expertise and can actually have less flexibility in making adaptations to the system. There is also a risk that confidential or strategic information can be compromised. In addition, it is important for the client organization to have capable staff in-house to actively manage the outsourcing relationship with the vendor.

Offshoring is a recent sourcing strategy that can be used by organizations for in-house software development or, more commonly, in outsourcing arrangements. It is a methodology by which an organization exports ISD to another country via offshore development centers (e.g., Target has established an offshore IT development center in Bangalore, India, to complement its IT unit in Minneapolis, Minnesota), captive units (i.e., a business unit of a firm that functions as an independent entity offshore but still maintains close ties with the parent company), outsourcing to locally based vendor (such as Infosys, Tata, or Wipro in India), or outsourcing to a global IT service provider (such as Accenture) that has delivery centers overseas. There are both "near" shore destinations (Canada and Mexico would be near shore offshore destinations for U.S. organizations) and "far" shore destinations (India, Russia, China, and the Philippines would be far shore offshore destinations for U.S. organizations).

Offshore systems development has distinct advantages. By conducting systems development in multiple locations around the globe, organizations can achieve faster development time since they can leverage a 24 × 7 development cycle (Carmel 1999). This can increase an organization's flexibility (because of increased productivity in developing and adapting information systems) and an organization's agility (e.g., by offshoring some projects to one location, IT staff at another location may become available for other projects). Offshoring also allows an organization to diversify its IT talent pool and reduce the risks involved in relying on a single market. Offshoring can facilitate localization of product software and provide proximity to target markets. Finally, offshoring may result in significant cost savings on IT development staff as IT professionals in some parts of the world receive significantly lower salaries. For example, an Indian IT professional costs 1/6 to 1/10 as much as an IT professional in the United States).* On the other hand, the costs of coordinating and communicating can significantly increase when systems development staff are distributed globally (Espinosa, Slaughter, Kraut, and Herbsleb 2007). Other potential issues include language problems, legal, accounting and cultural barriers, loss of control, confidentiality, security, liability, intellectual property, and increased vulnerability to political events (Carmel 1999).

61.3 Implications for Practice: Managing Projects for Flexibility and Agility

In general, strong project management and risk analysis, combined with effective communication and information gathering, help deal with complexity and uncertainty in systems (McBride 2007; Rai et al. 2009). In this section, we offer a number of specific recommendations for managing IS projects with an eye toward flexibility and agility.

* For more information about international salaries, see http://www.sourcingline.com/country-data/salaries-software-engineer-web-developer and http://www.payscale.com/research/IN/Job=Computer_Programmer/Salary#by_Years_Experience

TABLE 61.2 Selecting the Best IT Sourcing Strategy

	Custom Develop with Waterfall Approach If:	Custom Develop with Agile Approache If:	Buy Package If:	Outsource If:
Business need	Unique or core/complex, and relatively stable requirements	Unique or core/complex, and volatile requirements	Common	Not core or complex
In-house experience	Have both functional and technical experience		Have functional experience but limited technical experience	No functional or technical experience
Project development skills	Want to build development skills in-house		Development skills are not strategic. Have support and integration skills in-house	Development and support skills are not strategic
Project management skills	Skilled manager of IS/IT development projects. Proven methods available		Manager skilled at coordinating with vendor	Skilled manager can negotiate with and manage outsourcer
Time frame to implement	Flexible	Short	Short	Short or flexible

Source: Adapted from Dennis, A. et al.: *Systems Analysis and Design with UML Version 2.0: An Object-Oriented Approach*, 2nd edn. 2005. Copyright Wiley-VCH Verlag GmbH & Co. KGaA.

It is important for project managers to recognize and consider the various sourcing options. If custom development is called for, managers must decide whether to use the traditional systems development life cycle, or an agile method. A well-understood business need and relatively stable requirements call for using the systems development life cycle. So too do mission-critical systems, or systems being designed for the long term. On the other hand, volatile, emerging, or uncertain requirements suggest the use of an agile method. If time is of the essence, an agile approach is more likely to deliver a system more quickly.

There are many viable alternatives to custom in-house ISD. An important and challenging decision facing managers is which sourcing strategy to select, given a particular project. Although sometimes the sourcing strategy is determined by political or other organizational factors, it may be helpful to compare the strategies along several dimensions in making the best choice. Table 61.2 shows the major IT sourcing alternatives arranged along dimensions including the nature of the business need, the extent of in-house experience and capabilities, and the time frame of the project (Dennis et al. 2005).

As can be seen in Table 61.2, the more unique, complex, or core the business need, or the more volatile the requirements, the more custom in-house development should be favored. In contrast, the more generic or common the business need, the more attractive the strategies to buy the system. Generally, the more skilled, capable, and experienced the in-house IT staff, the more feasible is custom in-house development. Finally, the shorter the time frame, the more attractive it is to buy the system. In terms of software process, the more volatile the requirements, the more advantageous are flexible approaches such as agile methods.

Beyond the sourcing options, IS/IT project managers must learn to live with uncertainty in order to facilitate and encourage flexibility and agility in their teams and the software solutions. One approach is to realize the importance of a common, shared vision for organizing a project (rather than a fixed, inviolate plan) (Kirsch 2004; Kirsch and Haney 2006; Madsen et al. 2006). The vision needs to articulate the business value of the project (Madsen et al. 2006) so that the focus of the project, and ultimately its success, is whether it achieves business value, and not on how well it is implemented. A clear vision gives a project team direction, but does not enslave it to specific behaviors. Thus, it affords flexibility and agility.

Project managers must proactively plan for ways to deal with volatility found in an evolving problem domain, customer expectations, and perhaps the technology itself. In the presence of volatile requirements, it is important to promote ongoing mutual learning between developers and customers. Some methods, such as prototyping or agile approaches, encourage learning and intense customer–developer interaction (Lee and Xia 2010; Maruping et al. 2009). Similarly, Beyer and Holtzblatt (1995) propose an "apprenticeship model" of development in which the analyst and client engage in intense communication, discovery, and learning. Another option is to use participatory design, which recognizes the key role of the user in systems development, and in which both stakeholders together develop an understanding of the problem and solution possibilities (Kyng 1991; Simonsen 2007). Intense and frequent interaction promotes effective requirements gathering and interface definition; this in turn helps stakeholders understand and learn to deal with fluctuating requirements (McBride 2007).

Another means of dealing with volatility is to plan to deliver software solutions iteratively, relying on frequent releases and intense customer interaction and feedback (Harris et al. 2007; McBride 2007). Frequent releases ensure customers have access to the new features as they are developed. As the customers use features, project managers and developers can note their reactions and receive their feedback, learning how to adapt the system as customer needs emerge, evolve, and crystallize. Customers too can develop a better understanding of what is needed in a system.

As noted earlier, a high-level architecture can also help ensure that systems are designed and implemented for flexibility and agility. An architecture provides a high-level understanding of the requirements, solution, modules, subsystems, interfaces, and deployment plan. This helps the project manager and development team deal with system complexity and volatility, and it provides the basis for future adaptability, as it encourages modularization and layering of components based on standardized parts (Barry et al. 2006; McBride 2007). It can be a challenge, however, to ensure that systems are deployed in accordance with an architecture. One tool project managers have is the set of control mechanisms they can put in place to enforce compliance with an architecture (Kirsch 1996, 1997). Such mechanisms include the articulation of specific policies and procedures, and monitoring adherence to them, as well as fostering consensus about the importance of an architecture. Well-designed control mechanisms can help align interests of relevant stakeholders and ensure compliance with policies and standard practices. Another approach to ensure compliance is to add a software architect to projects (McBride 2007). The software architect, as the solution expert, works collaboratively with the business manager and project manager to ensure an initial understanding of the problem domain, elicit high-level requirements, identify and validate unstated expectations (McBride 2007).

Managing projects for flexibility and agility suggests an increased reliance on informal approaches to control and coordination to supplement and augment formal mechanisms (Maruping et al. 2009). Liberal use of ad hoc or casual meetings, hallway conversations, and social events are important means for controlling project teams and coordinating project tasks (Kirsch et al. 2010). Though it is important to rely more on informal and emerging mechanisms, it is equally important to recognize that existing structures, relationships, and methods cannot be ignored (Kirsch 1997; Madsen et al. 2006) as they provide the foundation for an emergent process that is in part predictable. Managers must have or develop an ability to adapt when technological, business, or environmental conditions change (Madsen et al. 2006). For example, systems development methodologies should be adapted for the situation at hand, rather than followed in the same manner for different situations (Fitzgerald 1997; Kirsch 1997; Madsen et al. 2006; Slaughter et al. 2006).

Finally, managers can take advantage of distributed geographic location and expertise by utilizing global distributed teams. However, it is important to foster trusting relationships and take steps to overcome cultural, language, or time barriers (Collins and Kirsch 1999; Rai et al. 2009). Providing access to dispersed team members through the use of tools such as collaborative technologies and videoconferencing will encourage knowledge sharing and joint problem solving (Majchrzak et al. 2005).

61.4 IS/IT Project Management: Research Opportunities

The contemporary environment for IS/IT project management is complex, dynamic, and uncertain (Elbanna 2010; Lee and Xia 2010; Maruping et al. 2009). This calls for an approach for developing and managing information systems projects that is flexible and agile, but our understanding of how to provide flexibility and agility is limited. In this section, we highlight three areas of future research. Each area represents a key role for IS/IT project managers. The first concerns development and design issues. The second concerns managing a distributed project team. The third concerns controlling projects.

61.4.1 Design and Development Issues

Requirements determination is a lynchpin in the development process. Project managers must ensure that a process is in place that not only elicits requirements but is sensitive to changing requirements. Given the increased volatility and uncertainty of the requirements determination task, it is clear that developers need the ability "to effectively and efficiently respond to business and technology changes" (Lee and Xia 2005, p. 77). Research suggests that such flexibility may be hard to find, however. In their study of over 500 ISD projects, Lee and Xia (2005) found that the project teams responded more extensively to business changes than technology changes, but they were more efficient addressing the technology changes. Additional research is needed to better understand how to achieve client–analyst learning in an effective and efficient manner, how to balance the need for customer responsiveness against the need for a disciplined development process, and how to train developers and analysts to thrive in an environment that demands agility and flexibility.

Another means of providing flexibility and agility is an architecture that promotes a modular design via a component-based or service-based approach to design. These approaches are similar in that they can be classified as "requirements adaptation" approaches as opposed to "requirements anticipation" approaches (Elfatatry 2007). However, they differ in that the component-based approach is to assemble existing prefabricated modules into a system during design (before system run-time). A SOA allows system designers to offer services through published or known interfaces. This kind of approach relies on run-time binding of components: when services are invoked, providers are chosen. Thus, a service-based approach provides potentially even more flexibility than a component-based approach. However, a service-based approach is not without its limitations, notably, implementation inefficiency and execution overhead (Elfatatry 2007). Additional research is needed to understand the capabilities and limitations of service and component approaches for achieving flexibility and agility. For example, under what circumstances does it make sense for an organization to adopt either approach?

Finally, there is a need for much more research on the use and effectiveness of agile methods to guide IS/IT project managers in choice of methodologies, and in better understanding the role of IS/IT project managers in agile contexts (Ågerfalk, Fitzgerald and Slaughter 2009). Initial research is promising. For example, in their case study at Intel, Shannon et al. (2006) found that the use of agile practices resulted in reductions in code defect density by a factor of 7, and that longer-term projects (i.e., 6 month and 1 year duration) were delivered ahead of schedule. Unlike some scholars, Fitzgerald et al. (2006) demonstrate that agile methods "are not anti-method, and require an equally disciplined approach, and as much tailoring as any traditional method" (p. 212). A special issue of the *Journal of Database Management* on Agile Information Systems Development (Erickson et al. 2005) contains a number of conceptual and review articles and case studies of agile systems development approaches. For project management, agile methods provide an interesting challenge: it is not clear whether and how formal project management practices (such as earned value analysis, work breakdown structures, and critical path analysis) that are predicated on waterfall development approaches can be applied or adapted to an agile development project. Additional field-based or experimental studies on the adoption and efficacy of agile methods for developing information systems and for managing agile projects would complement this research and provide valuable insights.

61.4.2 Managing Distributed Teams

Historically, project teams were generally collocated, and the management of the effort was typically vested in a single IS stakeholder. However, globalization is the new reality of contemporary firms, which suggests that project stakeholders—managers, users, project team members—are likely to be globally distributed (Herbsleb and Mockus 2003). The use of global teams can provide organizations with flexibility and agility. As previously noted, firms can adopt a 24 × 7 development cycle, leverage distributed knowledge, and respond quickly to local needs (Carmel 1999; Collins and Kirsch 1999).

Managing dispersed teams presents additional challenges for IS/IT project managers, including challenges related to differences in language, time zone, customs, and government regulations (Carmel 1999; Kotlarsky and Oshri 2005; Tractinsky and Jarvenpaa 1995). Moreover, distributed teams can incur higher costs of coordinating, controlling, and communicating: numerous researchers have documented the difficulties and costs associated with geographically dispersed teams (Espinosa et al. 2007; Kirsch 2004; Rai et al. 2009). Rapport and knowledge sharing are essential for successful collaborations but can be difficult to achieve in globally distributed teams (Carmel 1999; Kirsch and Haney 2006). Though technology can help address some of these challenges—e.g., high-speed connections and collaborative tools such as e-mail and instant messaging—they do not necessarily address social needs (Kotlarsky and Oshri 2005), nor do they necessarily compensate for geographic distance (Collins and Kirsch 1999).

Researchers have identified a number of ways to mitigate problems associated with distributed teams. For example, trust among distributed team members can improve personal relationships and productivity (Rai et al. 2009). When team members have electronic access to each other, knowledge sharing and collaboration are encouraged (Majchrzak et al. 2005). Transactive memory, the knowledge possessed by group members along with individual awareness of who knows what in the group (Wegner 1987), has been found to improve project effectiveness because knowledge seekers can quickly find expertise in the group (Faraj and Sproull 2000). Further, social ties and knowledge sharing have been found to improve collaboration among distributed team members (Kotlarsky and Oshri 2005). Additional research is needed to better understand the challenges of managing dispersed project teams, and the effectiveness of various tools and techniques to overcome those challenges.

61.4.3 Exercising Control and Coordination

Successfully controlling and coordinating projects is essential for IS/IT project managers to deliver the technological capabilities sought by their organizations. Control refers to all attempts to motivate individuals to work in accordance with specific objectives (Kirsch 1996). Coordination integrates and links different parts or activities to accomplish a task (Van de Ven et al. 1976; Zmud 1980). Control and coordination, though distinct concepts, share a focus on motivating and integrating people and processes to accomplish particular goals. Mechanisms to do so include formal approaches—rules, policies, methodologies, and standards—as well as informal approaches—ad hoc communication, peer pressure, and common values and norms (Kirsch 1997; Zmud 1980).

In the past, it was not uncommon for IS/IT project managers to rely on a simplistic understanding of control and coordination processes and therefore to use one-size-fits-all mechanisms. That is, control was often viewed as a static and generic cybernetic process in which goals or standards could be precisely specified, progress could be accurately assessed against those objectives, and corrective action could be identified and prescribed (Kirsch 1997). Consistent with this view, managers also may have assumed that a development methodology, precisely specified, could be faithfully followed and produce the desired system. However, it is now recognized that development methodologies are templates or guides for action, rather than a prescription for precise behaviors (Fitzgerald 1998; Fitzgerald et al. 2006; Kirsch 1997; Madsen et al. 2006). Thus, a methodology is best viewed as a "method in action" (Fitzgerald 1997).

In contemporary settings, there is a need to adapt control strategies to particular types or phases of projects or to adopt control approaches appropriate for nonroutine work (Kirsch 2004). Adaptation is

particularly important in an environment of uncertainty and volatility. Cyber projects such as NEES and GENI, in which needs and goals are evolving and precise IS-related activities or behaviors can be difficult to articulate, exemplify this environment and present a rich context for studying the complexity of IS/IT project management.

Dealing with increased complexity, uncertainty, and ambiguity also calls for increased reliance on informal communication, coordination, and control (Herbsleb and Moitra 2001; Kirsch et al. 2010; Kotlarsky and Oshri 2005; Kraut and Streeter 1995). For example, the use of informal social or clan control mechanisms early in the project can promote learning and consensus among stakeholders (Kirsch 2004) by focusing attention on common values among project team members and negotiating a consensus on project goals. Research suggests a need for flexibility in control and coordination strategies, adapting them as a project progresses in response to emerging understanding, performance problems, or changes in the project environment (Choudhury and Sabherwal 2003; Kirsch 2004).

Moreover, it is apparent that multiple stakeholders control a project, thus suggesting that no one person completely controls what happens (Kirsch et al. 2010; Madsen et al. 2006). As control strategies evolves over the life of the project, the controller, i.e., the person exercising control, also changes (Kirsch 2004). At any one point in time, any particular manager may be both "in control" and "out of control" in the sense that he or she must grapple both with certainty (e.g., working in a stable environment with regular work, meetings, and patterns) and with uncertainty (e.g., an unpredictable environment with emergent action, conflict, and diversity), what has been termed the "paradox of control" (Madsen et al. 2006). However, it is not clear how managers grapple with a paradox of control. Additional research that examines the ebb and flow of control across project stakeholders over time would be extremely useful. In addition, there is a need for a more nuanced understanding of the types of control and coordination needed to achieve agility and flexibility, specifically the trade-off between too much and too little formal and informal control and coordination as a project unfolds over time.

61.5 Conclusions

Information systems are indispensable to firms, enabling their operational and strategic business processes. In recent years, dramatic changes in the business landscape, coupled with the expanding range and capability of available IT, brought the need for flexibility and agility in corporate computing to the fore. Today's IS/IT project management must facilitate a firm's ability to rapidly respond to competitive strikes and to quickly deploy their own strategic initiatives.

This chapter explored current and emerging trends in IS/IT project management. We discussed the meaning of flexibility and agility in the context of systems development and implementation projects, and highlighted the implications for managing IS projects. Flexibility and agility start with a plan, an architecture, or a blueprint to guide the development and deployment of systems. The architecture or blueprint provides the basis for adaptation by facilitating incremental, modularized development with standardized parts. Flexibility and agility can also be enhanced by using principles from agile development approaches that favor a lightweight, adaptable approach. The numerous sourcing options available to firms provide a great deal of flexibility and agility in system acquisition, as they allow firms the freedom to select an approach that best fits its needs. Firms are no longer constrained to the often high-risk, time-consuming method of developing systems internally. On the other hand, when the situation calls for it, internal development is feasible and can provide firms with flexibility in solving business problems or enabling strategic initiatives.

This chapter discussed the need for flexibility and agility in project management, with a particular focus on design decisions, the management of distributed teams, and on control and coordination of projects teams. Achieving flexibility and agility do not require eliminating the use of standards, rules, and procedures, but it does require judicious use of formal structures so that action is not unnecessarily constrained. Using informal control and coordination mechanisms to supplement formal mechanisms

provides a project manager with flexibility. The use of geographically distributed teams can also provide flexibility and agility, but it is not without its challenges.

It is clear that achieving flexibility and agility requires a supple and nimble mindset, as well as a number of specific principles and approaches. Additional research is needed to develop a better understanding of ways to achieve flexibility and agility, as well as ways to overcome barriers preventing developers, managers, and others from embracing flexible and agile approaches.

IS/IT Human Resource Development and Retention

Thomas W. Ferratt

Eileen M. Trauth
The Pennsylvania State University

62.1 Introduction

Over time, information system (IS)/information technology (IT) management has come to be understood as referring to more than the technology alone, or even the information systems based upon it. One of the topics in this broadly understood domain is IS/IT personnel. In fact, in 2012, the Association for Computing Machinery (ACM) Computer Personnel Research Conference became 50 years old. The publications from this conference along with papers published in the ACM publication, *The Database for Advances in Information Systems*, and other journals that publish IS/IT human resource (HR) research, give testament to the sustained interest in the human resource dimension of the computing field. Finally, evidence of the core importance of IS/IT HR is that there is an ACM indexing category for it. Topic K is the computing milieu; within it, K.7 is the computing profession with subcategories including occupations (K.7.1); organizations (K.7.2); testing, certification, and licensing (K.7.3); and professional ethics (K.7.4). Hence, a chapter on IS/IT human resource development and retention clearly has its place also in this handbook.

This chapter is organized as follows. We begin by considering the research to date on the underlying principles for IS/IT human resource development and retention drawn from the extant research. This section is followed by a discussion of IS/IT HR development and retention practices. The final section of this chapter considers emergent themes about IS/IT human resource development and retention that will motivate new research and practice in the future.

62.2 Underlying Principles for IS/IT Human Resource Development and Retention

When considering IS/IT human resource development and retention, an organization's chief information officer (CIO) faces these major questions:

1. What knowledge, skills, and abilities (KSAs) are needed by the personnel for whom I am responsible?
2. For what length of time would I prefer to retain the personnel for whom I am responsible, and what human resource management practices will support that?

We first consider how answers may differ based on the IS/IT organization's alignment with the overall organizational human resource strategy. We then review prior research that addresses these questions.

An IS/IT organization consists of the personnel and supporting resources that provide information and communication services to the larger organization. Examples of supporting resources include IT infrastructure, data, and application systems. Under the assumption that answers to the development and retention questions earlier vary systematically based on the IS/IT organization's alignment with the overall organizational human resource strategy, we first consider research that provides a strategic context for addressing the development and retention questions.

A major decision in an organizational human resource strategy is whether to develop human resources with the desired KSAs from within the organization or to obtain them from the external labor market. The former strategy has been referred to as a "make" strategy and the latter as a "buy" strategy (Miles and Snow 1984; Toh et al. 2008). Similarly, a craft internal labor market (ILM) strategy is similar to the "buy" strategy, whereas an industrial ILM strategy is similar to the "make" human resource management (HRM) strategy (e.g., see Ang and Slaughter 2004). CIOs have long been interested in aligning the IS/IT organization with overall organizational strategy (Luftman and Ben-Zvi 2011; Luftmann and Kempaiah 2008). A body of literature on IS/IT strategy, including alignment of IS/IT with business strategy, has emerged (e.g., see Chen et al. 2010). A natural extension is to the IS/IT organization's alignment with the overall organization's human resource strategy.

Discussing factors that a CIO should consider when determining whether to internally develop or externally acquire IS/IT personnel and deciding how long to keep them is beyond the scope of this chapter. We assume that the CIO will consider a variety of factors to determine the IS/IT human resource strategy, including the organization's overall business and human resource strategy. The IS/IT human resource strategy will provide a context for answering the two questions presented earlier that CIOs face with respect to KSAs and human resource management practices needed to support a specific length of employment relationship for IS/IT personnel. We next examine research on KSAs needed in IS/IT organizations. Following that, we review research on human resource management practices designed to retain IS/IT personnel for different lengths of time.

62.2.1 IS/IT Human Resource Development

62.2.1.1 Studies of Knowledge, Skills, and Abilities

Organizations choosing to build (or "make") their IS/IT personnel through training and development programs would specify the content of their programs based on the answer to the major question facing the organization's CIO: "What KSAs are needed by the personnel reporting to me?" As would be expected in an environment where the technology changes rapidly, the specific technical skills needed by IS/IT personnel also change rapidly. The required skills vary by specific job title. As Huang et al. (2009) report, Java developers need knowledge in Java, JavaScript, or J2EE and sometimes they need HTML, .NET, or XML knowledge. These specific technical skills were not needed by IS/IT personnel

in the study reported by Lee et al. (1995); Java had not even been released as a programming language at that time. Besides keeping up with changes in technologies and the associated skills needed to apply those technologies, a challenge for researchers and practitioners has been to specify a set of KSAs that may be used for various IS/IT roles and job titles. Ideally, this set would make it more feasible to identify the mix of KSAs needed by IS/IT personnel in various jobs now and in the future, facilitating planning by CIOs and educators.

Researchers have worked with industry to specify KSAs in various categories, including technical, business, interpersonal, managerial, and project management (e.g., Kaiser et al. 2010; Lee et al. 1995; Trauth et al. 1993). Table 62.1 illustrates KSAs in four such categories reported by Lee et al. (1995). Categories beyond the technical specialties knowledge were defined broadly enough to apply not only in the 1990s, when the study was conducted, but also beyond. Even some of the technical specialties categories are broad enough that they still apply.

A number of researchers have investigated what KSAs IS/IT personnel need (Cheney 1988; Huang et al. 2009; Kaiser et al. 2010; Lee et al. 1995; Nakayama and Sutcliffe 2007). Roles studied include entry-level IS/IT professionals, programmers, analysts, and IS/IT managers. Table 62.2 illustrates results for entry-level IS/IT personnel in high-wage regions of the world (Kaiser et al. 2010). Methods used to identify IS/IT personnel skills have included asking knowledgeable sources (e.g., IS/IT executives/managers, business/user managers, IS/IT consultants), reviewing job advertisements in newspapers or online job postings, and examining practitioner publications.

TABLE 62.1 Categories of Knowledge, Skills, and Abilities

A. Technical specialties knowledge[a]	**C. Business functional knowledge**
Network	Ability to understand the business environment
Telecommunications	Ability to learn about business functions
Relational databases	Knowledge of business functions
Fourth-generation languages	Ability to interpret business problems and develop appropriate technical solution
Systems integration	**D. Interpersonal and management skills**[a]
Distributed processing	Ability to work closely with customers and maintain productive user or client relationship
Data management (e.g., data modeling)	Ability to accomplish assignments
Structured programming/CASE (computer assisted software engineering) methods or tools	Ability to plan and execute work in a collaborative environment
Decision support systems	Ability to be self-directed and proactive
Systems analysis/structured analysis	Ability to work cooperatively in a one-on-one and project team environment
B. Technology management knowledge	Ability to deal with ambiguity
Ability to focus on technology as a means, not an end	Ability to plan, organize, and lead projects
Ability to learn new technologies	Ability to be sensitive to organizational culture/politics
Ability to understand technological trends	Ability to plan, organize, and write clear, concise, effective memos, reports, and documentations
	Ability to develop and deliver effective, informative, and persuasive presentations

Source: Lee, D.M.S. et al., *MIS Q.*, 19(3), 313, 1995.

[a] Top 10, based on projecting KSAs needed 3 years beyond the survey.

TABLE 62.2 Top 10 Entry-Level Skills in High-Wage Regions

Skill Category	Skill
Business domain	Communication
Technical	Programming
Technical	Systems analysis
Technical	Desktop support/help desk
Project management	Project planning, budgeting, and scheduling
Business domain	Industry knowledge
Technical	System testing
Business domain	Process knowledge
Project management	User relationship management
Project management	Working with virtual teams

Source: Kaiser, K.M. et al., *Commun. Assoc. Inf. Syst.*, 29(1), 605, 2010.

As Tables 62.1 and 62.2 illustrate, studies of job skills report that IS/IT personnel need a mix of KSAs, not just specific technical KSAs. To illustrate further, Huang et al. (2009) report that the skills needed for programming jobs include not only technical skills but also KSAs in communication and teamwork. IS/IT professionals who move from specific, technical roles to broader roles need a different mix of KSAs for effective performance in their new roles.

62.2.1.2 Capabilities Based on View of IS/IT Human Resources as Strategic Assets

Another perspective on KSAs needed in an IS/IT organization may be derived from research that takes a view of IS/IT human resources as strategic assets. Much of this work is based on the resource-based view of the firm (Bharadwaj 2000; Chen et al. 2010; Mata et al. 1995; Ross et al. 1996). Bharadwaj (2000) identifies two critical skills of human resources in an IS/IT organization. The first is technical skills, such as programming, systems analysis and design, and competencies in emerging technologies. The second is managerial skills, such as effective management of IS/IT functions, coordination and interaction with users, and project management and leadership. Although these skills are similar to those found in the studies of KSAs reviewed earlier, the view of IS/IT human resources as strategic assets incorporates a competitive perspective not necessarily present in the studies discussed earlier.

The implication is that more successful firms will have IS/IT technical and managerial KSAs that are better than competitors. As a result, they will have capabilities to integrate the IS/IT organization and business planning processes more effectively, conceive of and develop reliable and cost-effective applications that support the business needs of the firm faster, communicate and work with business units more efficiently, and anticipate future business needs of the firm and innovate valuable new product features sooner (Bharadwaj 2000). This competitive advantage is based on these capabilities being difficult to acquire and imitate, implying that the needed IS/IT human resource strategy would be to develop IS/IT personnel with these capabilities internally. A related implication is that from the CIO's perspective the desired turnover of IS/IT personnel with these capabilities would be low.

62.2.2 IS/IT Human Resource Retention

A contextual model of turnover for IS/IT personnel presented by Joseph et al. (2007) contains environmental-level, firm-level, and individual-level factors affecting retention. CIOs should understand factors at all levels, but firm-level factors, particularly human resource strategy and human resource practices for IS/IT personnel, are factors that are most likely to have the ability to influence directly. Human resource practices, in turn, affect individual-level factors. For example, the extent to which IS/IT personnel have opportunities for internal promotion is a practice perceived at the individual level

as an organizational advancement factor, one of the individual-level factors influencing the turnover process in the Joseph et al.'s (2007) model.

Many human resource management practices that CIOs may consider as part of their human resource strategy have been studied. In the broad domain of management research, Combs et al. (2006) report on the following practices in their meta-analysis of the effects of high performance work practices on organizational performance: flexible work, participation, teams, training, internal promotion, information sharing, compensation level, incentive compensation, employment security, selectivity, HR planning, performance appraisal, and grievance procedures. They reported on these practices because researchers had identified them as high performance work practices and they appeared in at least five studies that could be used in their analysis. Their analysis shows a positive correlation of these practices with retention. For CIOs seeking to develop (or "make") and retain IS/IT personnel, providing more of these practices would be consistent with the intent of establishing a long-term relationship. For CIOs interested in establishing a short-term relationship with IS/IT personnel, providing less of many of these practices would be consistent with that strategy.

Research in the more focused domain of managing IS/IT personnel has also studied human resource management practices that affect retention. Agarwal and Ferratt (1999) asked CIOs and HR executives to identify effective or innovative practices they used to retain IS/IT personnel. The numerous practices identified were grouped into several categories, which Table 62.3 presents.

Based on their survey work and subsequent case studies of several organizations, Agarwal and Ferratt (2001) reported that organizations seeking to establish long-term relationships with IS/IT personnel

TABLE 62.3 Categories of Retention Practices

Retention Practice Category	Explanation
Work arrangements	Nature of the work individuals have the opportunity to experience and how they relate to one another
Employability training and development	Training and development activities provided to IT employees to enhance current skills required by the IT organization or to develop additional skills in current technologies
Quality of leadership	Training for managers and empowerment or participation of employees
Sense of community	Activities undertaken to provide IT professionals with the sense of belonging to and being connected with a larger community
Compensation and benefits systems	Policies that compensate IT employees for work. Includes setting basic compensation levels, incentive pay systems, and bonus systems
Organizational stability and employment security	The extent to which the business enterprise is financially stable and can offer employment security
Longer-term career development	Training and development activities made available to IT employees that focus on developing business and leadership skills
Opportunities for advancement	Career management systems and career paths for IT employees
Opportunities for recognition	Systems that allow supervisors to recognize and reward outstanding or exemplary performance
Lifestyle accommodations	Opportunities available to IT employees to adjust work schedules or otherwise help balance competing demands on their time
Performance measurement	Processes by which IT employee performance is appraised to allocate rewards and identify developmental needs

Source: Agarwal, R. and Ferratt, T.W., *Coping with Labor Scarcity in Information Technology: Strategies and Practices for Effective Recruitment and Retention*, Pinnaflex Press, Cincinnati, OH, 1999.

use different bundles of human resource management practices than organizations desiring short-term relationships. Organizations desiring a long-term relationship follow a long-term investment strategy. This strategy is consistent with the "make" HR strategy. Organizations following this strategy invest more in career development and security than IS/IT organizations interested in a short-term relationship. Organizations following a long-term investment strategy tailor human resource practices, such as compensation and benefits, to make IS/IT personnel reluctant to leave, for example, by providing longer vacation periods than competitors or profit sharing that is available after staying with the organization a specific period of time. In general, these organizations use human resource management practices that reflect concern not only for productivity but also for employees as individuals. For example, they may have greater employee participation, much more community building, and more lifestyle accommodations compared with IS/IT organizations at the short-term extreme.

Using the categorization of human resource management practices of Agarwal and Ferratt (1999), Ferratt et al. (2005) examined the effect of those practices on turnover. A large sample of CIOs described practices used in their organizations and reported turnover. Factor analysis identified five factors representing the human resource management practices used: (1) work environment and career development, (2) community building, including information sharing and social activities, (3) incentives, (4) employment security, and (5) nontechnical skill recruitment (i.e., the extent to which nontechnical skills are used to recruit IS/IT professionals). The first dimension, work environment and career development, includes practices that provide an attractive work environment for IS/IT professionals (e.g., interesting work, employee empowerment, and promotion from within); in addition, it includes training and development opportunities for technical, managerial, and business KSAs.

Using cluster analysis, Ferratt et al. (2005) found different bundles, or configurations, of practices. One of those, the human capital focused (HCF) configuration, was high on all five human resource management practices. The HCF configuration also had the lowest turnover. Findings for other configurations are discussed in conjunction with the study by Ferratt et al. (2012).

Ferratt et al. (2012) extended Agarwal and Ferratt (1999, 2001) and Ferratt et al. (2005). Instead of asking CIOs, they asked IS/IT personnel about the human resource management practices used by their IS/IT organizations. Using factor analysis, they found four factors representing human resource practices—work environment and career development, social support, compensation, and security—similar to four of the five used in Ferratt et al. (2005). They used those as clustering variables to identify configurations of human resource management practices. Instead of investigating the relationship of practices to turnover, they investigated their relationship with job search behavior, a precursor to turnover.

What they found was a configuration that was high on all four human resource management factors and low on job search behavior, which is consistent with the HCF finding from Ferratt et al. (2005). They also found a task-focused (TF) configuration that was low on all four factors and high on job search behavior, which is consistent with a TF configuration found by Ferratt et al. (2005). The other configurations they found were consistent with configurations in Agarwal and Ferratt (2001) or Ferratt et al. (2005) with the exception that they did not find a secure configuration (high on security and low on other practices), which was identified in the 2005 study and had turnover between the HCF and TF configurations. What they also found is that the human resource practices in the two extreme configurations—HCF and TF—have synergistic effects. For the HCF configuration that means that job search is less frequent than would be expected from the independently additive effects of the practices, and for the TF configuration job search is more frequent than would be expected. Furthermore, they found that the human resource practices in all other configurations did not have synergistic effects.

The conclusion we derive from these studies is that retention is related to a variety of human resource management practices, including work environment and career development, social support, compensation, and security. These practices independently affect retention, and in extreme combinations (i.e., all high or all low) they synergistically affect retention. Thus, CIOs and the human resource managers supporting them may consider a number of practices independently and in combination to influence retention.

62.3 IS/IT Human Resource Development and Retention Practices

Practice is reflected in the research presented earlier. For example, KSAs that CIOs build or buy may be found in the results of research (e.g., see Tables 62.1 and 62.2). Similarly, human resource practices that CIOs use to retain IS/IT personnel may be found in the results of research (e.g., see Table 62.3). The research reported in the prior section has implications for practice that we discuss later.

We noted earlier that the IS/IT human resource strategy provides a context for understanding development and retention practices for IS/IT personnel. What may not be so obvious is that changes in how organizations use computer technology also provide such a context. In this section, we suggest that our understanding of who belongs in the category of "IS/IT personnel" and what they do has expanded as technology has changed and organizational use of computers has evolved. Discussion of this coevolution later provides this broader context for understanding IS/IT human resource development and retention practices and serves as a bridge to the final section on research issues for IS/IT personnel.

62.3.1 Implications of Research for Development and Retention Practices

An organization pursuing a strategy to buy its human resources from the external labor market would not expend significant resources to train and develop IS/IT personnel. Instead, it would recruit and hire individuals who possess the desired KSAs. Furthermore, an organization pursuing a buy strategy would not expend significant resources to retain these personnel. Instead, it would simply recruit and hire new IS/IT personnel to replace those who leave. On the other hand, an organization pursuing a strategy to build (or "make") its human resources with the desired KSAs would want to invest significantly in training and development and in other human resource management practices designed to keep those employees from being hired away before the organization has the opportunity to recoup its significant investment in them.

Research on configurations of human resource management practices with respect to IS/IT personnel suggests that the buy and build strategies would have quite different configurations. An implication of findings from that research is that CIOs following a buy strategy and desiring a short-term relationship with IS/IT personnel would implement a TF configuration, which is low on all practices. In contrast, CIOs following a build strategy and desiring a long-term relationship with IS/IT personnel would implement an HCF configuration, which is high on all practices.

Build vs. buy strategies may affect the mix of roles for IS/IT personnel. The mix of roles determines needed KSAs, since KSAs differ by role. Beyond the overall strategy for obtaining human resources, some IS/IT organizations may seek to buy specific KSAs that are not core to their business, for example, via outsourcing, temporary external personnel, or short-term internal hires (Wu and Zmud 2010). They may choose to follow a different approach when obtaining KSAs that are core or necessary for their business strategy. A business strategy that considers the IS/IT organization a strategic asset would be consistent with the resource-based view of IS/IT personnel as strategic assets. An implication would be that IS/IT personnel KSAs that are core or necessary for the business strategy would be developed and retained through using an HCF configuration.

Although not a significant focus in prior studies, change management emerged in Kaiser et al.'s (2010) top 10 skills that are critical to keep within the IS/IT organization, rather than outsource, in high-wage regions of the world. Starkweather and Stevenson (2011) suggest that the ability to deal with ambiguity and change is one of the more important core competencies for project management success. Given the prevalence of changing technologies and organizational change associated with projects involving IS/IT professionals, Markus and Benjamin (1996) have argued for educating IS/IT professionals to become more effective agents of organizational change. An implication for educators is to develop curricula for developing KSAs focused on managing change. Although the IS 2010 model curriculum has some learning objectives and topics on change management (Topi et al. 2010), the focus on change management

could be further developed. The implication for CIOs is that they should work with educators to develop the needed educational changes.

KSAs related to change management, including project management, are important for success not only for IS/IT personnel involved in change efforts but also for end users, particularly user managers responsible for leading change efforts. Besides assuring that IS/IT personnel have needed change management KSAs, an implication for CIOs is that they should extend their focus beyond IS/IT personnel. Since the success of projects significantly involving IS/IT personnel is dependent on users, including user managers, CIOs should extend their role to influence the making or buying of non-IS/IT personnel with KSAs needed for leading change efforts.

The KSAs discussed in prior research have included knowledge of technological trends and technology as a means rather than an end. In the context of an organization's business strategy, understanding how IT may be used to maintain and improve the organization's competitive position could be critical to organizational success. An implication for CIOs is that their responsibility for internally developing or externally acquiring KSAs regarding information technologies may go beyond IS/IT personnel. They may need to work to influence managers throughout their organizations to identify and adopt IT to support business processes, with the goal of improving the organization's competitive position.

62.3.2 Coevolution of Organizational Computer Use and IS/IT Personnel

Human resource practice related to IS/IT worker development and retention has coevolved along with the evolution of computing. During the postwar 1950s and 1960s computer technology migrated from exclusively military applications to also include business applications, which became widespread with such computers as the IBM 360. This first expansion of computer use was accompanied by terminology changes as *business data processing* entered the lexicon to characterize the use of the computer to solve finance, accounting, and operations research problems. And accompanying this new use of computers came an expansion in the personnel responsible for operating them. These first IS/IT personnel were required to have the specialized skills of credentialed computer scientists and engineers to create the programs that solved business problems and retrieved business information for others. By the mid-1970s, the pent-up demand for better and more timely information to support management decision making led to the reorientation of IS/IT in organizations as *management information systems* (MIS) and the emergence of IS/IT personnel with MIS degrees from business schools. It also coincided with the emergence of a new generation of smaller and more accessible computers. Two technological innovations that made information more accessible and timely for management decision making were Fourth Generation Languages and minicomputers.

The 1980s and 1990s witnessed increased miniaturization of technology and the merger of computing with communicating. Along with these technological innovations, came new personnel who were part of the computing labor force: *end-user computing personnel* and *data communications personnel*. Thanks to the portable "personal" computer that ran on off-the-shelf software, business people with limited knowledge about computer technology were now able to use them. This represented one of two "revolutions" of this time period: the end-user revolution. The second "revolution" was the telecommunications revolution that resulted from a combination of technological and policy changes. The technological innovations were packet switching, network interoperability, and open protocols. Policy change came in the form of global deregulation of telecommunications that served to increase competition and innovation. Whereas the end-user revolution of the 1980s was enacted primarily in the computing domain, the end-user revolution expanded in the 1990s into the telecommunications domain. By the 1990s, the World Wide Web, commercialization of the Internet, and conceptualization of national information infrastructures led to a further expansion of computer use—and associated computer personnel—signaled by the term *electronic commerce*.

Key technological trends of the 2000s and 2010s have centered around the convergence of telecommunications and computing, mobility, cloud computing, social media, and the ubiquitous IT capabilities

that have resulted. Hence, the evolution of IT has resulted in an ever-expanding definition of IS/IT personnel. In the twenty-first century, personnel in this expanded role definition increasingly have come to be labeled as the *IT worker*. These individuals are distributed throughout the organization. Some are IS/IT specialists reporting to other business functions, some work in the centralized IS/IT department of a company, and some work for both new and established IT companies such as IBM, Microsoft, and Google. Finally, given the widespread accessibility of user-friendly computing thanks to PCs, the web, and mobile devices, a new community of IS/IT consumers outside of businesses has emerged.

62.4 Research Issues Related to IS/IT Professionals

Future research will be motivated by drivers of technological evolution, environmental forces, and questions that CIOs face. The pace of technological change shows no sign of slowing down. Mobility, ubiquity, and convergence appear to be the dominant technological trends for the foreseeable future. Further, the implications of social media are just beginning to be realized. At the same time, environmental forces such as increased globalization and an unstable economy will increasingly affect workforce development and retention. Unanswered and newly emerging questions related to needed KSAs and human resource practices for retaining IS/IT professionals for an appropriate length of time will be affected by these technological and environmental forces and will drive future research.

Technological trends and environmental factors will exacerbate the increasingly fuzzy line between users and "IT professionals" as they are increasingly labeled.* Hence, even as the two major IS/IT human resource development and retention questions facing CIOs will remain, new interpretations of these topics are entering the research space and new challenges will emerge. New areas for IS/IT human resources research relate to IS/IT workforce identity in the face of ubiquitous computing, end-user technical sophistication and empowerment, workforce diversity, globalization of the IS/IT workforce, and global economic instability. Hence, the research challenges that this part of the information systems field will face in the future will expand accordingly.

62.4.1 Expanding Boundaries of the IS/IT Profession

New forms of IS/IT work are resulting from new technologies and new uses that are discovered for them. This, in turn, leads to a broader definition of the IS/IT professional and new roles for these individuals. Subsequently, while existing topics related to development and retention will remain (e.g., Joshi and Kuhn 2011), new IS/IT human resource research topics will compete for center stage.

62.4.1.1 Multiple IS/IT Disciplines and Paths to an IS/IT Career

While in the 1950s and 1960s the path to an IS/IT career had a single development path, by the 1970s this was changing. A bifurcation of computing work was in evidence, which further broadened the scope of who was considered to be a "computer person." There was a growing recognition of different categories of "computer personnel": some worked at companies such as IBM while others worked within the information systems departments of companies. This division, in turn, led to the evolution of an additional development path.

The earliest educational path into a career in computing—in the 1950s and 1960—was through computer science. In the 1970s, with the broadening of the focus of computing beyond computation into business applications, programs of study in business schools—MIS—began to appear. Throughout the 1980s, the dominant educational paths were computer science and information systems (the latter was also called MIS or computer information systems). Then, as the century was coming to a close, a third educational path emerged. The information school—or iSchool—movement grew out of computer

* The term "IT professional" here is meant in the broadest sense of subsuming "information systems professional" and, hence, is meant to be equivalent to "information professional."

science programs that were adding human issues—such as human computer interaction—to their curricula, as well as library science programs that were increasingly adding computer science and information systems perspectives to their programs. Finally, educational programs—called informatics—emerged that enabled individuals to study computer applications for settings other than business data processing (e.g., healthcare and government).*

As a consequence of this educational splintering, there is an IS/IT human resource development research challenge to better understand the relationship among these different educational paths and the similarities and differences among the KSAs that graduates from these programs will possess. Additional research issues relate to workplace development and retention issues. How will individuals from these varied educational backgrounds relate in the workplace? What additional corporate training will be needed to smooth out differences? With respect to retention, the more in-demand the area, the harder it will be to retain individuals with that expertise, assuming supply does not keep up with demand. Hence, there is a need for research to better understand how to retain these individuals.

62.4.1.2 IT Industry versus IT Occupation

The educational divide that was introduced in the 1970s signaled a larger IT career divide that is coming to considerably greater recognition in the twenty-first century, as explained later. In the late 1970s, the first major clarification about the IT labor force was published. This clarification emerged from a nationwide study conducted in 1977 that sharpened our emerging understanding of the IT labor force. A report to the U.S. Department of Commerce (Porat 1977) introduced the concept of an "information economy" and defined it as that portion of the labor force that is engaged in the production of information and information tools. This analysis divided the IT labor force into the *primary information sector* and the *secondary information sector*. The primary information sector includes IT workers engaged in the production of information and information tools—such as those who work at computer manufacturers, telecommunications companies, or software development firms. It includes those workers engaged in the production of information processing and communication hardware, software, information systems and services, and information content. In contrast, the secondary information sector includes that portion of the IT labor force that is engaged in information processing work in some other industry—such as banking or healthcare. Whereas the output of the primary information sector is the information or information tools such as computer software or communications technology, the output of the secondary information sector is a noninformation good/service such as healthcare, education, or government services (Trauth 2000, p. 5). While similar work such as programming occurs in both sectors, those in the secondary information sector are not considered to be part of the IT industry. Rather, they can be considered to be part of the *IT occupation*.

The development of IS/IT professionals and the enactment of their career paths increasingly occur along the lines of this division. Those individuals interested in careers in the primary information sector would most likely study computer engineering, computer science, and sometimes information science/informatics. Those inclined toward employment in the secondary information sector would study (management/computer) information systems, information science, and informatics. As a result, a number of IS/IT human resource development and retention issues are emerging that require further research.

While the distinction between primary and secondary information labor forces was articulated 35 years ago, it has not been fully incorporated into the development of IS/IT professionals. Further, the emergence of multiple educational paths (as outlined in Section 62.4.1.1) exacerbates the situation. Hence, there is a need for research to provide a better understanding of the human resource dimensions of the primary and secondary IT labor forces. This research will accompany the growing distinction between careers in the IT industry and careers in the IT occupations, and the number of different IT "disciplines" in which one could prepare for either career path. For example, Trauth et al. (2007) examined the implications of this labor force distinction for the notion of an industry cluster. Their conclusion

* The School of Informatics and Computing at Indiana University is one such example.

is that in regions without a high density of firms in the primary information sector, Porter's (2000) notion of "industry cluster" would not be helpful. In response, they introduce the concept of an "IT occupational cluster." In addition, although Gallagher et al. (2010) suggest that the same KSAs are needed by all IT professionals, we suggest that more research is needed in better understanding the difference between the KSAs required of students intending upon careers in Google, for example, and students intending upon a career in health informatics.

62.4.1.3 Lateral Entry from Other Disciplines

The growing ubiquity of technology and a generation of increasingly sophisticated users is leading to an increasingly porous boundary between IS/IT professionals and lay people. The emergence of highly computer literate "power users" of IT is resulting in the growth of lateral entry into the IS/IT profession from other fields. And it is leading to yet another widening of the boundary that marks the IS/IT professional. The resulting IS/IT human resource research issues center around the development and career paths for these individuals. Although recent research has provided new insights into the career paths of individuals in the IT workforce (Joseph et al., 2012), many unanswered questions remain. Is this lateral entry occurring through formal education during career preparation (e.g., through students taking a double major or a minor in IS/IT) or is this lateral entry occurring in the workplace? Research is needed to learn the dimensions of this phenomenon and the implications for IS/IT workforce development both in universities and in companies. Further, additional research is needed about the integration of these "lateral entrants" into the IS/IT departments of companies. Research is needed that focuses on both management of the IS/IT workers and worker development to smooth out differences in educational backgrounds and fill in gaps in knowledge and skills. Finally, research is needed about the "make or buy" decisions relative to such training. Examples of questions of interest to IS/IT managers would be whether to fund employees to pursue an existing professional masters degree, contract with universities to provide a specialized degree tailored for a firm's employees, or hire experienced workers who have already completed specific educational programs.

62.4.1.3.1 Globalization and Offshoring

Another expansion of the boundaries of the IS/IT worker has occurred geographically. The movement toward offshore outsourcing began in the 1970s with the first tentative steps by computer hardware manufacturers in high-wage countries such as the United States to low-wage countries such as Ireland (Trauth 2000). Gradually, the offshore work grew to software development and then to information systems processing so that by the 2000s this was a major part of a company's IS/IT labor force strategy. The original "buy" decision with respect to the IS/IT labor force was to hire people with the needed KSAs or to outsource to a firm which could provide them. But in the past 30 years the outsource decision has become more complex as it quite often means *offshore* outsourcing. This globalization of outsourcing has produced a host of IS/IT human resource issues and accompanying themes requiring further research (Kaiser et al. 2010).

Research themes in this domain are related to differences in national IT infrastructure, the role of IT in a nation's economy, public policies related to IT use, and cultural differences. These themes, in turn, need to be connected to identification and enactment of the new KSAs needed to successfully navigate in a global IS/IT workplace. For example, Huang and Trauth (2008, 2010) have focused on issues related to negotiating differences among people from different nationalities in offshoring work groups as well as how different ethnic or national groups react to varied human resource policies. They have done so through examination of cultural influences on the coordination of IS/IT work in geographically and temporally distributed workplaces, and cross-cultural management issues. Other research focuses on differences in the IS/IT profession at the country level.* Many of these studies focus on international samples of IS/IT workers in emerging economies such as China or India, with sporadic reports from

* *Journal of Global Information Management* is replete with research studies in this vein.

Southeast Asia, Africa, or South America. This leaves much room for conducting further research into similarities and differences in the preparation of IS/IT workers and their work practices.

62.4.1.4 Diversified Workforce Composition

The movement toward offshore outsourcing that was firmly in place by the turn of the century was an early indicator of another force shaping IS/IT human resource development and retention in the twenty-first century: recognition of the need for a more diversified IS/IT labor force. Recognition of this need is accompanied by a considerable new research agenda for the field.

62.4.1.4.1 Diversity and Workforce Development

The early stereotype of an IS/IT professional (and indeed the image presented) was a middle-class white man with short hair, white shirt, and dark tie. This button-down image eventually gave way to more relaxed images of a computer professional, but they were still men and still white. The mandate for the twenty-first century IS/IT workforce coming from government, underrepresented groups, and private sector firms is for a radical makeover of the IS/IT labor force. In the future, the task of ensuring a supply of qualified IS/IT personnel is increasingly bound up with issues of diversity. As the use of IS/IT spreads and deepens in societies, the IS/IT profession is challenged with meeting the demand to enlarge the IS/IT workforce by recruiting and retaining personnel from historically underrepresented groups (Panko 2008).

Trauth (2011, pp. 561–562) explains that the motivation for greater human diversity in the IS/IT profession comes not only from labor force needs but also from environmental forces. First is the *consumer argument*. In an information society, in which all citizens are engaged in the consumption of information products, it is crucial that the varying needs of the entire consumer base be represented. The impending retirement of the baby boom presents the second, the *demographic argument*. The departure of a significant component of the workforce is compounded by the shift in countries such as the United States from a white majority. This trend coupled with projected growth in the IT sector over the next 10 years will produce a labor force demand that cannot be satisfied by white men alone. The third motivation for greater diversity is the *innovation argument*. As commodity production increasingly shifts to low-wage countries, developed countries are increasingly turning to innovation for economic sustainability. Greater divergent thinking resulting from more diverse groups of people in a supportive environment should lead to greater innovation. Indeed, Florida (2002) documented a connection between tolerance of diversity and the recruitment and retention of individuals with technology talent. Finally, there is the *equity argument*: all individuals, regardless of gender or ethnicity or other identity characteristics, should have the same opportunities to pursue a career in the IS/IT field.

Accompanying the desire to diversify the IS/IT workforce is the need for research to better understand what is keeping segments of society from entering the IS/IT workforce. An understanding of the barriers is the prelude to intervention efforts that must then follow on and be assessed. With a few exceptions, it was not until the late 1990s that IS/IT personnel research began to consistently include diversity. This is when the question of gender and ethnic diversity in the American IS/IT workforce was raised in research presented at IS/IT conferences. For example, as of 2011 the ACM SIGMIS Computer Personnel Research conference has included 43 papers on the topic of gender and the IS/IT workforce. But with the exception of a paper in 1971 and two in 1995, the remainder of the papers were presented since 1997. In recognition of the growing importance of this theme in IS/IT workforce research, the 2003 conference theme was diversity. While the need for research on gender issues and interventions continues (Trauth 2012; von Hellens et al. 2012), the new frontier for diversity research is race, ethnicity, socioeconomic class, and their intersection with gender (Trauth et al., 2012).

62.4.1.4.2 Diversity and Workforce Retention

Closely aligned with the need for research on the barriers to preparation for and entry into the IS/IT profession is the need for research into workforce retention issues as they relate to a more

diversified population. Bias and resistance to women and underrepresented minorities is one fruitful avenue of workforce retention research. Another is the influence of work life balance on retention. This topic has historically only been applied to women in the workplace. But the Millennials, including those in the IS/IT workforce, represent a different kind of worker from the baby boomers (Trauth et al. 2010). This generation of workers—men and women alike—is interested in work life balance. Another dimension of this research area is the cohort of seniors, who may have come out of retirement to reenter the labor force or who may want to work for the pleasure of it, and on their own terms. What motivates such workers and what it takes to retain them are not yet fully understood.

62.4.2 Environmental Influences on IS/IT Development and Retention

The evolution of IS/IT human resource research and practice does not exist in a societal vacuum. It is shaped not only by technological innovation but also by environmental forces. In the early part of the twenty-first century, environmental influences such as global terrorism and economic instability have shaped IS/IT human resource behavior.

The emergence of global terrorism as the century dawned and increasing awareness of the value and risks associated with organizational investments in IS/IT have spawned the growth of a new strain of IS/IT professional: the information security expert. Such individuals are employed by both government and the private sector to protect precious information and technology resources from attack. Hence, there has been the concomitant growth of educational programs in security and risk assessment to prepare a cadre of IS/IT professionals to fill these positions.

In similar fashion, the global economic crisis during the first and second decades of this century has resulted in changes in IS/IT organizations as firms have closed, merged, and depended more heavily on IS/IT to produce internal efficiencies. The call to do more with less is familiar to CIOs and IS/IT personnel alike (Watson 2009). Depending on how it is managed, this call could lead to work exhaustion and turnover of IS/IT personnel (Moore 2000). In a weak economy IS/IT workers may find it more difficult to change jobs, however. At the same time, IS/IT organizations may find they can less readily implement human resource practices—even if they wanted to do so—that would make employment with them more attractive. Research is needed that examines human resource management practices of IS/IT organizations and their effects within the context of each organization's overall human resource strategy over various cycles of economic conditions. It would be informative to include in that research examination of at least the correlates of changing labor market conditions throughout the economic cycles. Of particular interest in this part of the research would be the effect of IS/IT worker undersupply and oversupply on turnover and the ability of IS/IT organizations to implement human resource practices that lead to a desired level of turnover. Given the expanding view of who IS/IT workers are, determining labor market supply and demand for IS/IT workers could be challenging. Further, there is a need for research into creative responses to these economic pressures. For example, Beekhuyzen and Bernhardt (2006) describe an innovative IS/IT human resource practice that shifts the focus from the traditional "one-firm–one-role-centric" employment to "multiple-firm–one-role-centric" shared employment across micro and small enterprises in Australia. Employment sharing is the converse of job sharing. Whereas the latter refers to a labor arrangement in which two or more individuals share one full-time job, the former refers to one person working in multiple organizations.

62.5 Summary

This chapter examined IS/IT human resource development and retention from the perspective of a CIO's questions concerning the appropriate (1) KSAs required of the organization's IS/IT personnel and (2) human resource practices to support the employment relationship with those personnel. We expect CIOs to answer these questions in the context of their organization's human resource strategy.

That could lead them to "build" or "buy" KSAs and, correspondingly, implement human resource practices designed to maintain a long- or short-term employment relationship with IS/IT personnel.

We expect CIOs seeking a long-term relationship with productive IS/IT personnel to follow a "build" strategy. Human resource practices supporting a "build" strategy are those providing greater security, more career development, and, in general, greater outcomes for IS/IT personnel who remain with the organization for a longer period. In contrast, we expect CIOs whose organizational human resource strategy is to "buy" KSAs to use human resource practices that provide less security, less career development, and, in general, fewer outcomes that would lead IS/IT personnel to remain with the organization for an extended period of time.

As technology changes, technical KSAs needed by IS/IT personnel will change. Needed business, interpersonal, managerial, and project management KSAs will depend on the mix of IS/IT personnel roles. That mix is influenced by the make or buy decision.

Besides the organization's human resource strategy, other factors influence the context within which CIOs decide on the KSAs needed by IS/IT personnel and the human resource management practices to support the employment relationship with IS/IT personnel. We discussed three such factors: the evolution of IT, the changing understanding of IS/IT personnel, and environmental forces. Given the trajectory of these forces, we expect them to continue as influential factors in the future.

In this chapter, we have also made several assumptions that might be examined and potentially revised in the future. First, we have assumed that the IS/IT organization seeks to align its human resource practices with the organization's overall human resource strategy. In the future, this basic assumption could be challenged as other determinants of IS/IT human resource strategy clearly emerge from research or practice. Second, we have assumed that two divergent approaches to acquiring KSAs—make or buy—are determined by this alignment and will drive the implementation of human resource practices. Under a resource-based view of the IS/IT organization, IS/IT capabilities are considered strategic assets that provide sustainable competitive advantage. Such resources take time to develop and are considered hard to imitate. Buying these KSAs would not be consistent with a resource-based view of the IS/IT organization. Thus, we assume that when the IS/IT organization is viewed as a strategic asset KSAs are developed rather than bought. Future research could challenge this assumption as well. Finally, we have assumed that an IS/IT organization follows a single human resource strategy. But future conditions could force reexamination of this assumption. As intimated in the discussion of scarce KSAs, it continues to be necessary to understand the challenges that are associated with having more than a singularly focused strategy that implies a single build or buy approach to acquiring KSAs and a single set of human resource management practices for IS/IT personnel.

Radical changes in IS/IT human resource development and retention best practice and research may arise not only from rethinking underlying assumptions guiding research and practice but also from significant environmental influences. An example is the increased concern about information security, resulting from global terrorism and global hacking, that has inspired the rapid development of a specialty—information security—within the IS/IT profession. Finally, the spread and duration of global economic cycles may result in a significant rethinking of the employer–employee relationship for IS/IT personnel. Hence, the need for IS/IT personnel research to inform practice will be greater than ever in the future.

Performance Evaluation/ Assessment for IS Professionals

Fred Niederman
Saint Louis University

63.1 Overview

In the world of Moore's law, the rate of growth of computing equipment, software, and digital content insures an ever-changing and expanding set of business and consumer activities in cyberspace. Though many are not necessarily conscious of it when experiencing flow and interacting directly with technology, it is clear that generations of laborers have created the building blocks and applications that have become pervasive. In many cases, these workers have dedicated themselves without a profit motive contributing to open source projects and communities, have built technologies "on speculation" hoping with the help of venture capital to make it the next "killer app", or have been employees creating new features and capabilities as part of an IS workforce. For employers of these IS workers, it is important to provide the materials and environment under which the best computing products will emerge—"best" being a convergence of trade-offs between quality, costs, and scope. From that perspective, it is often viewed to be important in managing to assess their performance for purposes of workers in general and IS in particular to provide feedback, to form a basis for compensation decisions, bonuses, and retention, and to aid in matching assignments and promotions to individual workers. For these reasons, many firms have programs for performance evaluation of all workers including IS professionals. From the inception of IS as a part of the business landscape and, therefore, with the hiring and development of the initial crop of IS workers, concern for applying human resource management practices to IS workers has been expressed. For example, in 1962, the first conference on computer personnel research was undertaken in Los Angeles sponsored by the U.S. Navy and organized by the Rand Corporation. From the very

beginning of this group, issues about how to define the tasks of computing professionals, measure the performance of these tasks, and organize human resource activities pertaining to these workers were investigated. It is clearly of significant interest to be able to manage IS employees and, as a major part of that, to be able to evaluate and assess performance. However, this is not necessarily as clear and straightforward a task as it might seem on the surface to be.

Performance evaluation* of the productivity of information systems (IS) professionals is a complex and multifaceted topic. It is complex because (1) evaluation of the performance of any employee has multiple aspects and effects; (2) IS is a broad field suggesting many varied tasks, the active and passive application of many skills, and job titles that tend to be vague and nonstandard from firm to firm and even department to department; (3) in many cases, the tasks of IS professionals require the creation of technologies or applications that have never existed before in that particular or even in any form; (4) the work of the IS individual often cannot be treated as completely separate from other individuals; (5) both the inputs and outputs of the work are frequently not well specified—as we know requirements are difficult to ascertain and users are often unclear about what a preferred outcome is as they will "know it when they see it"; and (6) the benefits to high-quality performance evaluation may be largely intangible (e.g., higher moral and motivation, more targeted future behaviors, and retention of desirable staff members) but the costs tend to be tangible (e.g., the cost of a consultant sponsored program) or at least quantifiable (e.g., the amount of time spent in various related activities translated into estimates of the value of that time).

Addressing this topic is also difficult due to the hierarchical nature of examining IS professionals as a group of workers with the larger class of all knowledge workers or even all workers in general. Some human resource interventions may affect all workers in similar ways. For example, increases in benefits, direct compensation, or advancement opportunities may be viewed as precursors to more satisfaction or organizational commitment for the bulk of workers of all sorts. However, some interventions may affect knowledge workers or more specifically IS professionals to a qualitative or quantitatively different degree. Prior research (e.g., Couger, 1988) has tended to show IS professionals more strongly motivated by challenge and less motivated by working with other people than workers in other job categories. In this chapter, research specific to IS professionals will be emphasized with additional background information regarding findings pertaining to all workers briefly presented as a thorough examination of all knowledge about performance evaluation is outside the scope of this chapter.

63.2 Configuration of IS Personnel Literature on Performance Evaluation

A scan of the ACM Digital Library shows fewer than a dozen papers on performance evaluation with only one of these, Jiang et al. (2001), published since 1990. This is in contrast to literally hundreds of papers on various measures of technical performance of hardware, networks, and software. It is, of course, entirely appropriate to have much attention on performance of technology (note that some of these papers address tasks that involve the interaction of humans and technology, but the emphasis is on measures of the systems, not on the worker as a member of the staff per se—in other words system variance is measured, not the quality of human input). But the vast disproportion of interest is a bit surprising.

The volume of papers on this topic is not much more exhaustive when examining the "basket of 8" leading IS journals (see Table 63.1). Although the search term "performance evaluation" retrieved more than 100 papers, the majority of these did not address personnel evaluation but rather the evaluation of the IS departmental function and its value, particular systems especially virtual teams and decision support, and a wide range of other IS-related artifacts and programs that can be assessed. One paper

* In the IS literature, the phenomenon of interest is generally termed "performance evaluation" but the same general concept in the management literature is called "performance appraisal." The two terms are both intended to refer to the same phenomenon of evaluating and communicating individual worker performance.

TABLE 63.1 Literature Search/ABI Informs by Basket of 8 on Performance Evaluation (JSIS Search through Science Direct)[a]

Journal	Raw Returns	Number Pertaining to IS Personnel	Topics
JMIS	49	5	Webmasters, as independent variable antecedent on turnover, job satisfaction, and intention to telecommute; passing reference in career inventory instrument development
MISQ	43	4	Performance measures for differentiating contract and full-time employees; computer-based monitoring, using computers for general HR assessment; effect of performance evaluation on promotion, by gender; measure job performance as a dependent variable (DV)
ISR	29	0	
JAIS	11	0	
EJIS	12	0	
JIT	19	0	
JSIS	20	1	Career outcomes
ISJ	5	0	
Total	188	10	

[a] A note on method. For each journal, I searched in either ABI Informs or Science Direct on personnel evaluation and the journal title. The number of resulting papers is listed in the second column. I then manually went through each paper reading abstracts to ascertain whether the paper pertained to personnel or the evaluation of some other IS artifact or program.

illustrates an effort to develop fundamental data about the development task opening the door to a basis for performance evaluation. Rasch and Tosi (1992) used a survey method to examine a host of factors that might influence the performance of software developers. These factors included effort, ability, personality factors, and the like. Performance was self-reported on a 1–9 scale based on a single question. The two most influential factors on performance were ability and need for achievement. The goal of the paper is very laudable in that valid precursors to performance outcomes would form a strong basis for the development of performance evaluation criteria. However, it does not resolve questions such as how do you motivate people you need but have lesser ability (or keep people with more ability motivated if those with lesser ability or outcomes are also rewarded). The use of a single self-reported question regarding performance may have been necessary in the research context, but it also does not shed much light on the nuances of what constitutes the differences in performance that may have been reported. The responses to the questionnaire may have been as much about confidence or relative performance (e.g., an average developer may look great in a poor group but poor in a great group) as about performance per se.

Of the 10 papers identified, several used performance evaluation as an independent variable. Several papers by Igbaria and colleagues (Igbaria and Baroudi, 1995; Igbaria and Guimaraes, 1999; Igbaria et al., 1995; Igbaria and Wormley, 1992), for example, used the presence or absence of performance evaluation as a precursor to several dependent variables including career satisfaction and intention to turnover (or leave current employment). At most, this sort of study can provide evidence for the importance of performance evaluation in a nomological net of constructs. Unfortunately it does not help much to explain variance (why it works better in some cases than others) nor to provide help for managers considering ways to implement this sort of program. One notable paper (George, 1996) considered the effects of computer-collected data for the evaluation of people doing other jobs, for example, telephone help line staff.

What accounts for the relatively small number of publications on performance evaluation of IS personnel? Logically, we can speculate about a number of reasons. These include (1) the problem is so simple that the solution is obvious; (2) the problem is so difficult that no solution is possible; (3) the problem does not require a precise answer so relatively simple solutions that address part of the problem are sufficient; and (4) the problem is viewed not as a computer-oriented problem but rather as a management problem and, thus, outside the scope of ACM research or concern.

Without discounting the first three explanations, the last one is strongly supported by a quick search of ABI Informs. Such a search shows more than 3000 retrievals on "performance appraisal" when limited to scholarly journals. Clearly, performance appraisal remains a strong managerial topic. It is possible that many IS managers view such evaluation as a purely managerial problem amenable to management solutions without, necessarily, much adjustment for the particulars of IS work per se. Human resource management scholars take up personnel appraisal generally in search of universal precepts that could be applicable across job types and titles. This makes sense from a pragmatic perspective. Imagine the cost of designing different evaluation systems for each distinguishable type of job from doctors to firefighters to actuaries to scuba instructors.

Following such a view, a firm might be inclined to set up a standardized general program across the firm, but vary some details for each division, department, or perhaps even by individual job title. In such a system, a questionnaire might include items pertaining to attitude and skills (e.g., communication) that are common for all employees, but additionally include other items that relate to measures specific to particular jobs (e.g., ability to manipulate HTML, XML, and a UNIX environment by webmasters) (Wade and Parent, 2001/2002).

This approach, however, leaves open questions. How should IS managers adjust such programs for application to employees in the IS function? Is the search for a standard way to fill in the details for IS functions reasonable? Because there can be so much variance between individual jobs and organizational IS tasks, some may consider there to be no substitute for individuals or workgroups assessing their own work environments.

Is the problem of devising a performance appraisal system for IS employees simple or difficult? It is definitely simple if a firm is happy with the default—not doing any performance evaluation. Ultimately, we know of no legal or regulatory requirement that firms provide performance evaluation to their IS personnel so the default value of simply not doing it is pretty simple and straightforward. It also has the advantage of minimizing cost and avoiding some of the conflicts and difficulties that come with performance evaluation programs trying to balance standards for fairness with recognition of individual preferences for another kind of fairness. As pointed out in 1976, however, this strategy has some risks:

> Every time he [the IS manager] is faced with a choice of assignments, promotions, raises, or offices, he ranks his eligible employees. Unfortunately if his subordinates do not know the evaluation criteria, they may not be able to improve. More than likely, they will assume the criteria by observing who gets the rewards, in such cases, the manager runs two immediate risks—employees may misinterpret both the rewards and/or the required behavior (Ledet, 1976).

In some cases, these risks are insufficient to motivate performance assessment that is calibrated to provide the feedback that does move a workforce into directions of mutual benefit to the organization and employee. A poorly designed or executed performance evaluation program can be run with relatively low cost and generates minimal paperwork, but fails to provide much insight or to generate positive employee behaviors and learning. At an extreme, it may push the most productive to experience frustration, diminished job satisfaction, and, eventually, an intention to leave employment. A poorly designed and administered program can cause more problems than it solves. On the other hand, informal signals that no one will take it seriously anyway can sometimes mitigate some of the problems. There is, of course, the concern in such circumstances that some employees, in particular those who take things literally and/or who care a lot about achievement, will think it is serious and become disaffected upon learning that it is not.

When viewed as a task where the firm wants to achieve benefits above costs and is willing to make significant investment to that end, the "simple" problem becomes significantly more difficult. As mentioned, managers may have to choose between treating everyone identically (to the benefit of some and detriment of others) or differentiating treatment based on individual's preferences (and risking some being treated better rather all being equivalent). Other sources of difficulty stem from the need for a number of factors to be present in the organizational setting such as a trustworthy management and workforce willing to trust in the fairness and thoroughness of the process to spur integrity in the process and participation. Where there are difficulties with design of the program, there are also difficulties with its implementation. If the implementation is done in spotty, intermittent, ambiguous, or coercive

manner, it may generate a particularly large number of severe unintended consequences as well as, or perhaps instead of, those that are desired. Whatever the purpose and execution of the program, its existence, its content details, and the quality of its implementation will affect each employee sometimes in unanticipated and possibly negative ways; this may offset the benefits of the intended effects.

Somewhat surprisingly, a significant number of studies in human resource management pertaining to performance evaluation take a relatively contrarian perspective expressing concerns regarding performance evaluation as a management tool. Ikramullah et al. (2012), for example, provide a detailed literature review listing many of the issues and difficulties that make performance assessment unpopular in many quarters. "Poorly managed [performance assessments] can cause various problems for organization, like, disputes among employees and management, anger in staff" (p. 144).

One CIO in an informal and personal e-mail put the same idea this way:

> The performance evaluation for IS/IT personnel is probably the single worst thing that can be done in an organization of knowledge workers. There is no upside and the results are generally disastrous. Calculating scores is insanity disguised as rationality—the weighting factors are just BS.

In spite of this sentiment, it is likely that there are situations where performance assessment of IS personnel can be helpful when programmatically applied in organizational settings. Potential benefits would include providing some relief for individuals from arbitrary and incompetent managers and, when done well, with some legitimate guidance regarding organizational priorities and preferences. It is also important to note that in litigious societies performance appraisals can be used to produce a record supporting (or refuting) claims of unjustified employment termination (Malos et al., 2003). It is likely that some organizations undertake performance evaluation primarily, if not solely, for purposes of record keeping and creation of documents for potential dispute resolution. In light of this attitude, a reasonable research question would be: given the necessity of such record keeping (and the costs entailed), how does one get the most possible benefit from it while reducing its risk of harm to the greatest extent? It is also of note that the tendency toward formal performance appraisal and record keeping expands rapidly as firms grow in size and particularly in number of employees (Kotey and Slade, 2005).

From a research perspective, the problem is difficult to shape into a relatively simple formula or theory for a variety of reasons: (1) the purpose of performance evaluation can vary between and within firms and over time; (2) regardless of stated purpose, the actual activities will generate perceived purposes among the personnel involved; (3) standardized programs have trouble-adjusting techniques given that activities that are motivating to some may be equally demotivating to others; (4) implementing programs that are tailored to different groups have the potential to be viewed as unequal and showing favoritism (whether or not such is intended); (5) rating systems have much room for varied interpretation based on either cognitive or interest conflicts; (6) supervisors and workers are in dynamic relationships with some mutual dependencies (that vary with particular situations) and, as game theory may predict, will derive greater benefits from mutual admiration than from frank constructive feedback; and (7) attempting to gather enough detail to fit all standards and differentiate among all variations may create massive overhead that drains away potential benefits.

63.3 Approaches to Performance Assessment for IS Personnel

63.3.1 Rating Based on Outcomes, Characteristics, and/or Abilities

Much of the performance assessment approach revolves around an analysis of jobs and tasks with subsequent rating of performance for each individual for each atomic identified task or characteristic. In the IS literature, early research suggested that an order of magnitude discrepancy existed between high- and low-performing IS workers (programmers in particular, Dickmann, 1964, but with some nod to debugging and other tasks, Woodruff, 1980a,b). Dickmann (1964) led and discussed a detailed study conducted under the auspices of ACM's Special Interest Group on Computer Personnel Research (see Table 63.2 for criteria and sample questions). Four criteria clusters were proposed (professional

TABLE 63.2 Dickmann (1964) Measures and Description for Original Computer Personnel Research Group Performance Appraisal Instrument (Full Instrument Available through ACM Digital Library)

	Sample Questions
Professional preparation and activity	The number of broad areas of application (e.g., programming systems, numerical calculation, management application, Monte Carlo, statistical, etc.) in which he has demonstrated competence is (anchors 1, 2, 3, 4, or more)
Programmer competence	His program output rate is (unsatisfactory to exceptional)
Dealing with people	He helps others with programming difficulties (almost never to "a lot"/often)
Adapting to job	His ability to work independently with limited supervision is (unsatisfactory to exceptional)

preparation and activity, programmer competence, dealing with people, and adapting to job). Additionally, a 42-item questionnaire was produced and validated.

Woodruff (1980a,b) points out that some prior research suggested an order of magnitude difference between higher- and lower-performing IS workers. It was proposed that if the lower performers could be identified "scientifically" and dismissed, then overall performance would be better served. Of course, this can be a self-fulfilling prophesy as dropping the low performers would immediately shift the statistics, but might constrain the total amount of work accomplished. Of course when Woodruff conducted these studies, the range of IS tasks was much narrower. These days the range of needed abilities may be large enough to accommodate clever managers assigning those best suited to different tasks—super programmers may be writing code to integrate systems where better communicators are writing up application requirements or interviewing users to assign security codes. It is noteworthy that Woodruff's findings did not show such dramatic results but in fact showed a rather small standard deviation implying a tight clustering around the average with few high and low performers among his sample.

Woodruff (1980a,b) also proposed a set of criteria for evaluation of IS worker performance (see Table 63.3 for full descriptions). These criteria are quantity of work, quality of work, job knowledge and skills, judgmental ability, job initiative, adaptability, cooperation, and innovativeness. It is interesting to note in a close reading of the descriptions that two of the eight criteria refer to outputs, three refer to characteristics, and another three to abilities of the employee. Presumably one could directly measure outputs, particularly quantity, by counting them rather than necessarily resorting to subjective rating.

TABLE 63.3 Woodruff (1980a,b) Measures and Descriptions

Measure	Description
Quantity of work	Refers to the volume of useful output associated with the ratee's job assignment; output is of sufficient quality as to satisfy requirements of the ratee's job assignment over which he has direct control.
Quality of work	Refers to those characteristics of the output that enhance its usefulness to the recipient; the ratee has direct control over the output quality, and there is a minimum of subsequent rework of the output.
Job knowledge and skills	Refers to those characteristics of the ratee that enable the ratee to sufficiently solve problems, technical, conceptual, structurally oriented, etc. that are normally encountered in the job assignment.
Judgmental ability	Refers to the ability of the ratee to exercise discretionary behavior to arrive at a wise decision when confronted with problem situations, often unstructured and at short notice.
Job initiative	Refers to those displayed characteristics of the ratee to undertake on his own, without specific instructions, actions, and activities deemed to be desirable in the performance of the job assignment.
Adaptability	Refers to the ability of the ratee to adjust properly and expeditiously to changing and unstructured situations and problems encountered in the job environment.
Cooperation	Refers to those displayed characteristics of the ratee to act or operate jointly with facility users and fellow workers.
Innovativeness	Refers to the demonstrated ability of the ratee to introduce something new or novel to effect a desired change to alleviate or solve problems that are generally characterized by their uniqueness or complexity.

In 1980, when the range of tasks performed by an IS department were much narrower than they are now in the 2010s, a narrower set of abilities might be reasonable. It would seem now, however, that a wide range of abilities could be matched to different jobs, some emphasizing technical and abstraction, others planning, decision-making support, auditing, and the like. Characteristics form an interesting set. If someone has a "bad attitude" why were they hired? If such developed in the course of work, might it not be worth investigating why this happened? Cooperation, as a characteristic of the employee, is also interesting. Doesn't this depend in large measure on the others who might be involved? Is this likely to change from one reporting period to the next?

In another study of performance appraisal of IS personnel, Meyer and Stalnaker (1968) (see Tables 63.4 and Table 63.5) make the stunning observation that managers based performance criteria on the top 10 choices in a wide survey, but based hiring and selection decisions on the bottom 10 choices. Even today, more than a few IS faculty scratch their heads when told by IS managers what they look for in IS workers compared to what they see in advertisements for openings and results of applications of their various students.

Jiang et al. (2001) present a detailed alternative schema for performance evaluation. This paper sketches a relatively formal approach to providing a broad but detailed assessment of IS personnel presumably at the level of the entire IS function rather than separately for each individual. Based on

TABLE 63.4 Meyer and Stalnaker (1968, p. 666) 10 Highest Rated Items by Supervisors

Item	Index Rating
Checking Out Programs K/C	74
Planning Programs K/C	73
Defining Problems K/C	72
Understanding Assignments K/C	70
Works Independently W/S	69
Finds Appropriate Programming Methods W/S	68
Diligent TT	67
Can Handle Complexity K/C	66
Able To Work Under Pressure TT	65
Masters Assignments Speedily W/S	65

K/C, programming knowledge/capability; W/S, working style; TT, temperament traits.

TABLE 63.5 Meyer and Stalnaker (1968, p. 666) 10 Items Rated Least Important in Appraisals

Item	Index Rating
Teaching Formal Classes P/P	10
Age P/P	16
Number of Professional Societies Belongs To P/P	17
Number of Publications, Talks Given P/P	17
Uses Mathematical Analysis Methods K/C	29

Initiates Investigations In Math Analysis K/C	34
Evaluates New Hardware K/C	34

K/C, programming knowledge/capability; W/S, working style; P/P, personal/professional item.

personal and local experience with firms, this approach is at the top end of formality, but somewhat approximates what local employers do with a couple of exceptions that will be noted.

This chapter is based on a rather extensive survey of IS employees and other stakeholders at a particular organization. It outlines a procedure for formal performance assessment with the ultimate goal of aligning corporate and IS goals to assure IS behaviors that reflect these goals and priorities. This chapter notes a number of communication links assessed by different stakeholders. When the stakeholders were in agreement based on similarity of observation, this indicated concurrence. When the stakeholders differed in their level of agreement, these defined gaps of varying size based on the deviation in agreement. What to do about such gaps is not addressed. One assumes that the knowledge of such gaps represents an important step allowing managers the opportunity to intervene (or not to intervene) and to consider the sort of intervention they might want to take. This chapter tends to suggest that such intervention might focus on IS employee training but equally might focus on informing users about the actualities of work in an IS department.

Careful reading of this chapter shows some precursors are necessary for effective implementation of this system including detailed knowledge, agreement, and communication on corporate goals and a management structure in place to implement the described program. Such may have been the case for this particular studied organization, but the creation of these two precursors, realistically, may present significant challenge for the IS department managers.

The approach described by Jiang et al. (2001) is based on the measurement of seven criteria (see Table 63.6 for full description of each). These are quality, project work, general tasks, personal qualities, dependability, teamwork and leadership, and career-related training. At a more detailed level, these criteria pertain to following standards, using procedures and tools, implementing new systems, pursuing effectiveness, participating in project planning, control and communications, addressing user concerns, negotiating, being politically astute, solving problems, having a strong work ethic, completing tasks, securing cooperation, handling multiple tasks, interruptions, and diverse assignments.

The implementation of the actual evaluation process is not presented in much detail in this chapter, but seems to involve the comparison on these various specific points of ratings by the employees in contrast to the rating by managers and other stakeholders. It is in this implementation of data collection and analysis that the process differs most from my observation of local companies. Local companies tend to measure against similar criteria but are more inclined to produce goals as a negotiation between supervisor and worker and periodically measure progress against those goals. We will discuss goal setting and performance assessment in the next section.

Regarding Jiang et al. (2001), it is not difficult to raise additional questions and concerns based on the brief summary of this study that really raises as many questions as it answers. For example, it is not completely clear if this survey process is intended as a one-time analysis to identify gaps and provide a basis for selecting among potential ameliorating activities, or if it is intended to be repeated periodically as a way of assessing the effectiveness of interventions as well as getting snapshot pictures at a time. It is also not fully clear if each stakeholder is assessing each individual or the IS function as a whole. Should, for example, the "having a strong work ethic" criterion show a great difference between perceptions of the user community and the IS employee community, it is not clear how this would reflect on any given individual. It is equally unclear how users not knowing how long it takes to optimize an SQL query be able to assess whether an individual IS employee spent weeks of overtime or whipped the problem out in an hour or two. Assuming, however, that assessment of work ethic is a major differentiator in user and employee attitudes, the path for designing the appropriate intervention is not clear.

A number of other issues are skirted somewhat by the methodology of gathering data through surveys and analysis through gap comparisons. For example, the IS department is measured based on its use of standards, but may be frequently asked to bend standards for purposes of getting work done more quickly or at lower cost. Not only might such decisions be outside the IS department's control, but their realization may involve a natural trade-off such that it would be difficult or impossible to optimize both.

TABLE 63.6 Jiang et al. (2001) Measures and Descriptions

Measure	Description
Quality	Many quality problems undermining system performance stem from IS personnel glossing over design and delivery details. Therefore, IS employees should pay careful attention to these details and feel morally obligated to meet their responsibilities. The evaluation items associated with this measure are related to the overall quality of the work performed. Areas in the spotlight include the following of standards, employing procedures and tools, implementing the new system, and pursuing effectiveness.
Project work	Project management by IS personnel is critical to the success of any project. Adhering to users' schedules, budgets, and system specifications is an important aspect of project success and user satisfaction. The measures that help evaluate performance cover planning, control, and communications.
General tasks	Adherence to task is related to dealing with user concerns. IS professionals are often limited in the resources they need to deliver system specifications. A customer-focused IS professional should be prepared to inform users about information technologies, understand problems related to users' jobs, and anticipate users' needs. User relations drive the details that affect communications, persistence, and understanding of user functions.
Personal qualities	The way IS staff members relate to users is an indicator of user satisfaction. IS professionals need a customer-oriented attitude and be adept at such "soft" interpersonal communication skills as negotiating, managing change, being politically astute, and understanding user desires.
Dependability	Users should be able to rely on the IS staff. Successful IS professionals tackle assignments without having to be prodded by project leaders or users. IS professionals need to maintain a high standard of work performance and dedication to quality. IS professionals are expected to have a strong work ethic in order to meet commitments, seek appropriate solutions to problems, and complete tasks.
Teamwork and leadership	System development is often a team activity; team members should take pride in their work and enjoy working cooperatively. A team player is concerned more about achieving team goals than about individual accomplishment. How well an IS staff member secures cooperation and progresses toward user and organizational goals defines this measure.
Career-related training	The kind of IS worker needed to achieve system success should be able to handle multiple tasks, interruptions, and diverse assignments. Interest and willingness are not sufficient skills; knowledge and ability are also needed.

In a scenario illustrating a difficult problem, an IS organization is excellent on enforcing standards, but viewed as poor on providing immediate service to clients. As an intervention, service delivery times are strictly measured, bonuses, perhaps even pay or tenure are adjusted based on this. As a result, IS personnel simply stop bothering with standards, respond immediately to customer demands, and end up with a sloppy, poorly performing, and high maintenance cost platform or portfolio. On the next round of surveys, the rating of customer service rises to excellent but rating of standards falls to poor. On a 5-point scale, the IS department will never gather more than 6 or 7 points (out of 10 possible when the two scores are combined), thus building into the process the assurance that it will *never* be excellent across the board! Even if not drawn out explicitly, it is hard to imagine in such a scenario performance evaluation will ever be highly motivating. On the other hand, one can imagine a courageous management will be unequivocal regarding objectives. For example, they could specify that user response time is paramount and that extra maintenance costs will be tolerated if they will bring down the response time. Such could easily be visualized for a customer-oriented service such as providing financial or legal advice; however, actual brokers will likely also need flawless transaction processing. In such a system, perhaps standard keeping is not measured or is measured for reference but not included in a performance index.

It is also notable how few of the criteria for this approach are unique to IS employees, though their weighting or specification may vary. Surely, many other jobs require attention to detail, finishing tasks, communicating well, and other attributes. I am actually hard pressed to see anything that is unique to the IS function in the listing specified by Jiang et al. (2001), which may be a good thing if it is to be applied across a firm. This raises the question of whether the IS staff will also be rating the users. What is the quality of user work on stating their information requirements and providing quick and accurate feedback on prototypes? How reliable is their commitment on minimizing funding versus maximizing technical quality? It seems if one is going to look at the performance of the IS department, it should be in context of the other departments and their contribution to the management of information for the benefit of the overall firm. We fear some firms assume that the user is always right and any difficulties, by definition, the responsibility of the IS department. Of course, top management may assume all divisions are wrong or culpable, but that is outside the scope of our discussion.

All of this said, in some circumstances this procedure as an exercise in identifying areas of need or potential growth could be helpful to a firm. Such a list of criteria, while perhaps not distinctly customized for IS work, could serve as a basis for discussions about desired results or outcome of IS work and, in turn, the appropriate criteria for the IS department in a particular setting.

Where such programs are compulsory for IS departments, some portions of the HR literature pertain to general principles for various details of the performance appraisal process. In a recent example, Aguinis, et al. (2012) detail the value of addressing employee strengths rather than weaknesses in the communication of feedback to the employee. This chapter illustrates this technique with a variety of scenarios and dialogues. It is interesting to frame papers such as this in the context of research per se. That there is potential value for a manager to read and be aware of these many techniques (all of which on their face value have potentially positive consequences under some conditions) seems self-evident.

63.4 Critical Incident Technique (A Variation of Rating/Ranking)

The idea of the critical incident technique is to add an element of concreteness to the generalization and impressions of rating systems by noting particular incidents or events as part of the rating. As Dickmann (1964) points out, however, even this system has its complexities:

> By way of illustration, there is a professor at American University who states that he can reliably give you the performance rating of any Civil Service worker by merely having him pass by his desk; 99.8 times out of 100 he can tell you the exact rating for the federal worker. As you may know, the rating system for most federal employees has only three levels. They are outstanding, satisfactory, and unsatisfactory. The professor's mystical ability is diluted when you realize that only 0.2% of federal workers are ever rated in the outstanding or unsatisfactory category. It is therefore apparent that a major drawback to a critical incidents type approach is that if it turns out to be too much work, then all the rates become average.

63.5 Goal Setting

Another general approach to individual performance appraisal that can be applied to IS workers is based on goal setting. At time period one, goals are set that specify outcomes at a future time period. When that future time period arrives, the actual outcomes are compared to those specified in the goals. Some or all of the goals may have been exceeded, others reached precisely, and still others may remain unfulfilled. Many variations on implementation can exist in terms of who sets the goals and measures the results, whether or not movement toward the goals is observable, and what the consequences are of meeting or failing to meet the goals. Communication about goals can also vary from individuals setting their own personal goals without revealing these to anyone through public listing and display of goals

(e.g., fund raising goals for organizations like United Way that display movement toward a goal as actual funds are pledged). For example, goals may be the result solely of the employee, of the supervisor, or the result of discussion among them. In practice, one would expect the creation of goals to themselves be complex and the quality of their construction to have much influence on their ultimate effect on both performance and net organizational outcomes.

It is reported (Latham and Locke, 2006) that hundreds of studies consistently show that performance on cognitive and physical tasks is enhanced when goals are difficult and clear. It is further reported that there are some explanations for these findings—goals may prompt the exertion of greater effort, help focus on activities toward these goals to the exclusion of other activities, direct the individual to skill formation toward goal achievement or prompt the use of existing knowledge, and encourage persistence as nearness to the goal achievement is reached. When properly administered, each of these can be positive for the mutual benefit of worker and organization. We would caution that too narrow a focus on activities leading toward particular goals can logically cause a tendency to miss opportunities not specific to those goals. For example, measurement of an extraordinary amount of technical outcomes may discourage an individual worker from taking useful time to help a user client or mentor a colleague. Similarly, focus on efficient production of a number of reports may obscure the disappearance of the need for reports at all (or the inefficient restructuring of the report making it provide greater usability). The goal setter has to be careful about creating goals only for those tasks with concrete outcomes that can be counted and checked off when what is important may involve cultivating future transactions or enriching relationships. As noted by Latham (2004, p. 127), one cannot extrapolate directly on the effect of goal setting on "simple" relative to complex tasks:

> When working smarter rather than harder, when one's knowledge rather than one's effort (motivation) is required, participation in decision-making leads to higher performance if it increases the probability of finding an appropriate strategy for performing the task, and if it increases the confidence of people that the strategy can be implemented effectively.

Other cautions and limitations of goal setting are hinted at by Latham and Locke (2006), "So long as a person is committed to the goal, has the requisite ability to attain it, and does not have conflicting goals, there is a positive, linear relationship between goal difficulty and task performance." In this context setting statement, we can infer three requirements or precursors for observation of the positive effects of goal setting. Latham and Locke (2002) report that some research studies indicate that goals set by supervisors or workers did not seem to affect the growth of productivity. This seems reasonable when the overall process of goal setting is used with motivated staff who commit to the goals in either case. A strong test would be contrasting these types of goal setting in a workplace that was reluctant, suspicious, and untrustworthy. In education, one sees students committed to finishing a program, but not equally committed to studying for each examination or excelling at each paper or project as it comes along. The skill with which goals are designed so that individuals may apply both overall and component-based commitment would also seem likely to affect productivity. Along similar lines, it is clear that the ability to perform the requisite tasks to fulfill the goal is critical. In some circumstances, self-knowledge of abilities would also seem important for calibrating goals that are difficult but still obtainable.

On the other hand, it seems reasonable that in the process of goal seeking, individuals might become aware of lack of abilities that can be affected by training, practice, or absorption of explicit knowledge, thus providing something of a positive feedback loop that would have positive effects whether or not it was sufficient for full goal achievement. Locke and Latham (2002) address conflicting goals in terms of hierarchies of groups where individuals may have goals pertaining to departments that are not fully in accord with the larger goals of divisions, for example. Following the logic of agency theory, their own personal goals may not be in full accord with organizational goals. In moving from the individual level concept of difficult but clear goals stimulating higher levels of performance, addressing these potential conflicts would be critical.

Some additional questions pertaining to applicability of these theories in the actual workplace include (1) how the goal program is managed over repeated time periods; (2) how the program addresses those

who have the opportunity to surpass the set goals; and (3) how variance in results (in contrast to the comparison of average performances) is understood. It is not clear how the achievement of a difficult goal changes the abilities and expectations over time. It is not difficult to recall scenarios where IS personnel respond to a dramatic challenge with incredible productivity but end up exhausted, depleted, and burned out. This is a classic situation in the IS literature pertaining to the "forced march." After a few of these, retention may be difficult and productivity may return to lower levels. One might argue, following that productivity is likely to regress to the mean after an exceptional instance anyway. This would suggest the goal setting as a "jolt" strategy applied periodically during crisis but used sparingly at other times. It would seem to depend on the size of the gap between performance before and after goal setting and whether there was slack that needed tightening, or whether such productivity is the result of "selling off inventory."

Similarly, how does the firm address those who have the opportunity to perform above their stated goal? Setting higher goals for the next year, to the extent this is not successfully kept as a secret, can well have a chilling effect on anyone working an iota beyond the stated goal. It could also stimulate "game playing" such as hording successful actions above the goal for application to goals in subsequent periods. Interpretation of results in the setting of rewards for individuals based on different scenarios can also be tricky. How do you reward two people each with a productivity of "75 units" where one's goal was 50 and the other 100? Do you provide the same reward or differentiate based on goal achievement? In one case, having a high goal may have inspired greater effort and higher levels of achievement than without the goal; in the other may have had an inhibiting effect once the goal was met. It would be ironic if setting a higher goal (100 units) pushed that individual to create an extra 15 or so units, but the person were "punished" for having failed to achieve the goal. How likely is that person to set a new goal at all?*

What this boils down to is the lack of knowledge of what accounts for variance among both those setting and those not setting goals. Rather than try to add more precursor variables to the nomological net, perhaps it would be equally worthwhile to examine whether the population is heterogeneous and that different people react differently to the same opportunity? One of the reported streams of goal setting relates to "individual" differences, but I am not convinced that another generic characteristic accounts for this difference. Rather, there may be an interaction between individual work preferences and the details of the goal setting program. For example, in a trustworthy environment one individual might profit greatly from such a program but in an untrustworthy one there will be no cooperation; in contrast, some individuals might always or never respond in either trustworthy or untrustworthy environments.

Schweitzer et al. (2004) warn of another potential danger in the use of goal setting. Their experiment involving a production task with self-reporting of results showed a higher level of exaggerated reporting in difficult goal setting than in "do your best" conditions. Interestingly, their results did not show significantly better task performance for those enjoined to difficult goals rather than to the "do your best" condition. They concluded

> … people with unmet goals were more likely to engage in unethical behavior than people attempting to do their best. This relationship held for goals both with and without economic incentives. We also found that the relationship between goal setting and unethical behavior was particularly strong when people fell just short of reaching their goals.

Under a variety of circumstances, goal setting at an individual, group, or organizational level can result in higher levels of productivity. This approach does, however, require a significant understanding of the necessary and helpful prerequisites for its success. For example, is there a threshold of seriousness and follow-through by management that is required to make it work? We recall the "quality circles" of the 1980s and 1990s that were reputed to achieve such great things in a Japanese context but were hard to

* Academics, of course, have this dilemma in grading students—do you reward learning or change from initial to final knowledge and ability level (assuming we know where anyone starts) or do you measure results and reward someone taking courses that are below their entry level?

replicate in an American context because a variety of tangential elements were important to its success. At a minimum, we would expect some level of trust and trustworthiness, some ability to define and set well-constructed goals, some flexibility for moving among goals, and for opportunistically responding to new circumstances as critical for a balanced program.

63.6 Ranking and Forced Ranking

Another approach to performance appraisal consists of requiring supervisors to rank all of their employees from best to worst. Interestingly, this method is discussed in a rather humorous, though these days perhaps politically incorrect, manner by Dickmann (1964, p. 46). It is said that in some organizations the bottom set, say the bottom 10%, was automatically fired, or given a year to get out of the bottom 10%, which is interesting because they would only do so if either new people were not as good, someone else declined, or others improved at a significantly slower rate (or, to be cynical, others simply became less popular). In a time of general reduction of staff, this is one way to decide where to slim down. If there is an expectation that untrained newcomers will do better than existing staff, in a Machiavellian way this might also work.*

The obvious drawbacks to such a system are (1) if the hiring department did anything like a good job, all of the employees may be functioning at an acceptable level; (2) one supervisor's worst 10% may be better than half of the workers for another supervisor; (3) the tasks and assignments for each group are not the same; (4) it creates incentives to prosper oneself at the expense of colleagues whether or not this achieves best overall results; and (5) depending on how the ranking is achieved (which may not be standardized supervisor to supervisor), individuals may have incentives to work only on easy small tasks (if the key is number of completed tasks) or only on difficult long-term ones (if the key is having important pending tasks such that the supervisor cannot afford to lose one).

On the other hand, it can be an immense drain on a work group to have an employee dragging along the bottom of the performance totem pole barely achieving enough to satisfy the letter of the minimum job requirements. A ranking system with forced removal of bottom performers may be a very blunt instrument, but may have some benefits if it is the only way managers have the courage to remove those who really cannot keep up.

63.7 Weekly Conferences

Ledet (1976) describes a relatively straightforward approach to personnel evaluation. In essence, this technique posits a weekly meeting between supervisor and each individual staff member where the staff members present a list of the goals they have prepared for the next week. These goals should mostly come from the staff member modified by the supervisor to account for longer-term priorities. Naturally, this is a difficult technique to administer if the supervisor has a dozen or more people reporting or if staff members are working on projects where their simultaneous presence is needed. As a result, variations of biweekly or monthly meetings and/or meeting with multiple staff members at the same time might be employed. This should be particularly effective where the supervisor has technical expertise or skills and where the staff member has not yet developed sufficient skills for independent planning and execution of tasks on a short-term basis.

* In the IS arena, this is not an unknown tactic where the expectation is that new college graduates will bring innovation and the latest in technical capabilities to the workforce. An alternative is to hire a relatively small core of permanent employees in whom one invests heavily and supplement this core with numerous contract workers acquired to fulfill specific and well-defined functions. It is then relatively easy to shift training costs to the contract workers who, in principle, would shift between work and skill retooling. This strategy puts a significant responsibility on IS management to divide work between the segments of the workforce, maintain the core, and integrate the results.

I personally experienced this type of weekly conference as a trainer during an intense short-term process for preparing teachers of English as a Second Language in West Africa. Rather than discuss goals, however, each staff member presented a walkthrough of all lessons and activities planned for the following week and received feedback from all other staff members. Each individual was free to use or ignore the feedback, but, in general, the trainers clarified, added, took out, or otherwise improved presentations, and the exercise was viewed as enabling greater performance based on existing high levels of motivation. I cannot attest to whether this would work elsewhere if the same preconditions were not in place, but when reward is not an issue, only learning and improvement, it worked like a charm.

63.8 Conclusion

Performance evaluation is a tricky business in practice, particularly when it comes to knowledge workers and IS workers in particular. Clearly there are cases where such performance evaluation is helpful, but these may rely more heavily on a set of organizational characteristics being solidly in place rather than the details of the program itself.

The IS personnel literature has not focused on the mechanics of performance evaluation since the 1980s. Perhaps this is because the problem is so simple it is solved, so difficult we have given up, so generic we have accepted whatever management literature comes up with, or reconciled to firms either doing nothing (to customize to IS) or bringing in consultants to help them and, thus, do not perceive much need for knowledge creation in this area. In contrast, the human resource management body of scholarship is filled with many studies of precursors of success in performance evaluation programs, specific tactics such as better ways to focus or deliver feedback, and the like. While such knowledge may be helpful for crafting the framework of general programs, there is little help for IS managers in customizing these specifically for IS workers.

Returning to the CIO referenced at the beginning of this chapter, rather than suggesting an entirely skeptical outlook, his eight prescriptions for managing his IS employees sound pretty good. They are as follows:

1. Make sure all employees have the hardware, software, tools, training, and other resources they need to do the job.
2. Ensure a cultural environment that values them.
3. Be clear on the job and insure proper direction and quick management decisions.
4. Deal with any personnel problems contemporaneously. Thank everyone contemporaneously. Sponsor celebrations.
5. Make sure you have the right people on the bus and the wrong people off the bus.
6. If you have to do reviews have them do their own, make sure they are not too different from your mental model, but do not deal with any variance at the time.
7. Give everyone not under a formal HR remediation plan the same raise.
8. Tell your HR department to take their heads out of their books and get real.

To be fair, we can argue or debate about each of these, what they mean, how they might be implemented, and whether they work in all circumstances. Additionally, the CIO as a rule may not be involved in prevention of litigation on a day-to-day basis. In addition, this particular individual does not work for a gigantic corporation where the dampening effect of performance evaluation on strong managers may be compensated by shielding other employees from relatively too weak managers.

But notice that these admonitions are largely about the responsibilities of the manager creating the setting for work rather than the details of productivity of the individual worker. It is perhaps more about accepting the responsibilities of management rather than looking for formulaic procedures and quick fixes that look scientific but can introduce overhead, unfairness, and a distancing rather than integration of a workforce.

64.1 Introduction

Commentators frequently identify the harmonization of the financial reporting framework across international borders as essential to consistency and transparency in the financial reporting of global corporate entities (Roussey, 1992). Long considered desirable, the alignment of the major international financial reporting standards remained an unachievable dream in the eyes of many observers (Goeltz, 1991). The Mexican currency crisis of 1994 and then, particularly, the Asian crisis of 1997 (Humphrey et al., 2009) increased the prominence of the issue of the international harmonization of the financial reporting framework. In response, the international regulatory bodies set out International Standards on Auditing (ISA) and International Financial Reporting Standards (IFRS) as template standards to encourage international convergence of the financial reporting framework (Smith et al., 2008). Major developed economies have progressively and increasingly adopted these template standards (IFRS Foundation, 2011; International Federation of Accountants, 2011).

Adoption of these financial reporting standards is difficult. Substantial reforms demand measured consideration (Simpkins, 2010), and the adoption of these standards has been debated in the accounting profession (Herbohn et al., 2008). Such changes in the financial reporting framework have implications for financial audit practice (Kinney, 2005). Financial information systems (IS) audit work undertaken in support of the financial audit (Bagranoff and Vendrzyk, 2000; Muthukrishnan, 2008) is an increasingly important component of the financial audit as reliance upon more sophisticated IS increases (Cerullo and Cerullo, 2005). The implications of the adoption of the international financial reporting framework for financial IS audit practice have not been investigated and reported in the literature previously.

Establishing the requirements of international auditing and accounting standards for financial IS audit work is a necessary first step in a research program developing an understanding of the extent of alignment of financial IS audit practice with the international financial reporting framework. This chapter identifies those elements of the international auditing and accounting standards with the highest implications for the practice of IS audit through a direct review of the international auditing and accounting standards. The validity of the review is evaluated with data from interviews with 27 senior public sector auditors in Australia and Canada. These two countries have each adopted country-specific equivalents of the international auditing and accounting standards. This chapter then derives and presents a benchmark model of financial IS audit from this review of the international standards and relevant best practice IS audit frameworks. The benchmark model prescribes that, in a financial IS audit (using COBIT 4.1 terminology), auditors should be giving the majority of their attention to "deliver and support" processes (40%) while approximately a quarter of their attention should be devoted each to processes in the "planning and organizing" and "acquire and implement" areas. Finally, "monitor and evaluate" processes should be reviewed but to a smaller extent (12%).

The remainder of this chapter is set out as follows. Section 64.2 sets out a brief background to the reforms made to the auditing and accounting standards of Australia and Canada in the name of international harmonization. Section 64.2 also discusses the role of IS audit in the context of the financial audit as well as the development of best practice IS audit frameworks. Section 64.3 then develops a benchmark model of financial IS audit through review of the international auditing and accounting standards and professional best practice IS audit frameworks. Section 64.4 discusses the implications of these results for practice and theory. Finally, Section 64.5 identifies the limitations of this research and the implications of these findings for future research activities and concludes this chapter.

64.2 Auditing and Accounting Standard Reforms

This section discusses the motivation for international harmonization of auditing and accounting standards, and the adoption of the template auditing and accounting standards in Australia and Canada. This section also discusses financial IS audit and developments in the establishment and adoption of best practice IS audit frameworks. This discussion provides the basis for the development of a benchmark model for financial IS audit in Section 64.3.

64.2.1 International Harmonization of Auditing and Accounting Standards

Since the end of World War II and the adoption of the General Agreement on Tariffs and Trade, regulators have sought the harmonization of auditing and accounting standards across developed economies to ensure efficient capital markets and consistent "rules of the game" in international business (Hoarau, 1995, p. 218). A key development was the formation of the Independent Accounting Standards Committee (IASC) in 1973 (Camfferman and Zeff, 2007) and the International Auditing Practices Committee (IAPC) that was formed soon after the creation of the International Federation of Accountants (IFAC) in 1977 (Roussey, 1992).

International harmonization became more prominent after the Mexican currency crisis of 1994 and the Asian crisis of 1997 (Humphrey et al., 2009). The Financial Stability Forum was set up in 1998 by the

G7 to set up international standards, including the auditing and accounting standards (Humphrey et al., 2009). Subsequently, the International Auditing and Assurance Standards Board (IAASB) replaced the IAPC in 2002, and the International Accounting Standards Board (IASB) replaced the IASC in 2002 (Camfferman and Zeff, 2007). These two bodies issued revised ISA and IFRS, respectively.

In 2009, the IAASB finalized the Clarity Project. This project substantially changed the drafting convention of the ISA (Dennis, 2010) and provided new template auditing standards. The drafting and formatting of these template auditing standards were specifically chosen to communicate the requirements clearly and concisely. The initial template ISA identified "mandatory requirements" in bold type, with further explanatory material provided in plain type lettering (Dennis, 2010). The Clarity Project reformatted these requirements and explanatory material to remove the distinction between bold type and plain type lettering, and instead presented "requirements" separately to "application and other explanatory material" in the auditing standard (International Auditing and Assurance Standards Board, 2012).

The International Accounting Standards (IAS) released by the IASC prior to 2002 have remained in effect, although some IAS have been withdrawn and replaced by equivalent IFRS. Each IAS and IFRS sets out the standard's main principles in bold type. Although each paragraph has equal authority, paragraphs set out in bold type provide a summary guide of the standard's requirements (Howieson and Langfield-Smith, 2003).

The requirements of the auditing standards, and the main principles of the IFRS accounting standards, summarize the core principles of the international auditing and accounting standards. Many countries, including Australia and Canada, adopted these template auditing and accounting standards or country-specific equivalents.

64.2.2 Auditing and Accounting Standard Reforms in Australia and Canada

The following discussion provides a high-level overview of the current regulatory framework and the status of the adoption of the international auditing and accounting standards in Australia and Canada.

64.2.2.1 Audit and Accounting Reforms in Australia

The Commonwealth Government of Australia reformed the *Corporations Act* (2001) in response to domestic corporate collapses such as One.Tel and HIH (Jubb and Houghton, 2007) through the Corporate Law Economic Reform Program (CLERP). Prior to the adoption of the ninth installment of the CLERP (CLERP 9), the development and application of auditing and accounting standards had been considered the province of the professional accounting bodies. The CLERP 9 reforms instead moved to provide legislative backing to standards set by the government (Jubb and Houghton, 2007).

The ISA issued by the IAASB were used as a basis for the revised auditing standards of the Australian Auditing and Assurance Standards Board (AUASB) (Mifsud and James, 2006). The ISA were amended for the Australian environment as Australian Auditing Standards (AAS) with legal enforceability (Mifsud and James, 2006). Mandatory AAS requirements were initially emphasized in bold type (Mifsud and James, 2006). As the ISA provided a basis for the reformed auditing standards, the content of the auditing standards aligned highly with their international counterparts. The ISA and the AAS diverged however upon the completion of the IAASB Clarity Project (Dennis, 2010) and the AUASB thus revised AAS for consistency in 2010 (Financial Reporting Council, 2009). The revised AAS thus no longer emphasize requirements in bold type.

Similarly, the Australian Accounting Standards Board adopted Australian equivalents to the IFRS from January 1, 2005 (Boymal, 2007). The reformed accounting standards are referred to as the Australian International Financial Reporting Standards (A-IFRS).

64.2.2.2 Audit and Accounting Reforms in Canada

As with most developed nations after the Mexican and Asian currency crises, significant change occurred in the Canadian regulatory framework after 2000 (Carnaghan and Gunz, 2007). Canadian regulatory

powers for corporations are shared between the provinces, territories, and the federal government by Section 91 of the *Constitution Act 1867*. The resultant jurisdictional overlap results in differences between the corporate regulatory framework of each jurisdiction (Carnaghan and Gunz, 2007). However, the relevant corporations and securities acts and regulations require compliance with "generally accepted accounting principles," which are defined to be consistent with the Canadian Institute of Chartered Accountants (CICA) Handbook (Carnaghan and Gunz, 2007). The three Canadian regulatory authorities responsible for setting Canadian auditing and accounting standards in the CICA Handbook are the Canadian Auditing and Assurance Standards Board (AASB, Canada), Accounting Standards Board (AcSB), and the Public Sector Accounting Standards Board (PSAB) (Richardson, 2008).

The AASB (Canada), AcSB, and the PSAB have a central role in setting out the generally accepted accounting principles and the financial reporting framework. CICA provides oversight to these three boards. Thus, in Canada, the auditing and accounting standards have "force of law" under the Canadian regulatory framework (Richardson, 2009).

The AASB (Canada) adopted the Clarity audit standards developed by the IAASB for accounting periods ending on or after December 14, 2010 (Auditing and Assurance Standards Board (Canada), 2009). The AcSB and PSAB similarly sought to harmonize accounting standards with the IFRS standards set out by the IASB (Kanagaretnam et al., 2009), and required the adoption of IFRS-based accounting standards over the period January 1, 2011, to January 1, 2013, for publicly accountable enterprises and government business enterprises (Chartered Accountants of Canada, 2012).

64.2.3 Financial IS Audit

Financial IS audit is IS audit work undertaken in support of the financial audit (Muthukrishnan, 2008). Financial IS audit is an increasingly important component of the financial audit as the entity's reliance upon more sophisticated IS increases—for example, where a company's financial accounts are maintained through a large complex, integrated enterprise resource planning (ERP) system like SAP (Cerullo and Cerullo, 2005). The research presented in this chapter examines the relationship between the international auditing and accounting standards and financial IS audit practice. The profession of IS audit has matured greatly, with the development of the best practice IS audit frameworks of Control Objectives for Information Technology (COBIT) and the IT Assurance Framework (ITAF) (Hardy and Guldentops, 2005; Muthukrishnan, 2008). This research requires an understanding of the relationship between the financial audit and IS audit, and the development of best practice IS audit frameworks.

64.2.3.1 Relationship between the Financial Audit and IS Audit

In response to the challenge of delivering value in the financial audit, financial auditors increasingly adopt a business risk audit (BRA) approach to the audit task (Knechel, 2007). BRA requires a holistic approach to the audit (Knechel, 2007), and the audit profession particularly considers that this approach requires an understanding of the strategic systems dynamics and the audit's wider systems context (Bell et al., 1997). The financial audit explicitly considers and addresses risk in audit planning, and, therefore, the dependence of business processes on information technology (IT) increases the need to understand the controls around IS (ISACA, 2007) and the extent to which these controls can be relied upon in audit planning as part of risk. IS audit's role in risk assessment with the entire audit team is increasingly important (ISACA, 2007) as the adoption of BRA methodologies requires an increasing contribution from IS audit in the areas of planning and risk assessment (Vilsanoiu and Serban, 2010).

IS auditing is "the process of collecting and evaluating evidence to determine whether a computer system safeguards assets, maintains data integrity, achieves organizational goals effectively, and consumes resources efficiently" (Weber, 1999, p. 10). Muthukrishnan (2008) suggests that the specialist IS auditor may carry out IS audit work in support of IT-focused, financial, operational, or regulatory audits. IS audit work undertaken in support of the financial audit is the focus of this chapter and is referred to as the "financial IS audit." In the financial IS audit, the IS auditor supports the financial auditor through

feedback, assurances, and suggestions to address the traditional financial auditor's attest objectives that IS be available, maintain confidentiality, and ensure integrity (Sayana, 2002; Weber, 1999).

The IS auditor also increasingly undertakes application-level control reviews as BRA methodologies are adopted for financial audit (Vilsanoiu and Serban, 2010). This increased IS audit reliance is due to the higher IS risk of more complex systems (Bagranoff and Vendrzyk, 2000).

The task of financial audit is increasingly reliant upon the support of the IS audit function due to increased system complexity and the adoption of risk-based audit methodologies. The role of IS audit in this support function is to support the financial auditor in the development of an overall audit judgment.

64.2.3.2 Development of "Best Practice" IS Audit Frameworks

The term "best practice" generates considerable debate. In this chapter, the term "best practice" is aligned with the meaning given the phrase in popular parlance—that is, although different organizations have dynamic capabilities that reflect the context of the organization, there remain commonalities across "effective" firms (Eisenhardt and Martin, 2000, p. 1106). The commonalities contrast with the unique requirements of the organization (Eisenhardt and Martin, 2000), but the commonalities between effective firms encapsulate "best practice."

Several best practice IT management frameworks exist. However, the COBIT framework developed by the Information Technology Governance Institute (2007) and the related ITAF from ISACA (2008b) have the highest level of acceptance within the IS audit profession as a base framework (Hardy and Guldentops, 2005; Muthukrishnan, 2008). COBIT seeks to identify "what" needs to be done in managing IT (De Haes and Van Grembergen, 2004), whereas ITAF is a "comprehensive 'one-stop' framework for IT audit and assurance professionals" (Muthukrishnan, 2008, p. 1). ITAF is the preeminent IT management framework specific to the assurance area.

COBIT 4.1 identifies 4 IT process domains and 34 IT processes (Information Technology Governance Institute, 2007). As a more flexible framework, the ITAF identifies three categories of standards (general, performance, and reporting) and also identifies guidelines and tools and techniques for use by the auditor (ISACA, 2008b). The ITAF guidelines are identified as IT assurance processes, and these IT assurance processes are linked to COBIT IT processes.

64.3 Toward a Benchmark Model of Financial IS Audit

This section develops a benchmark model of financial IS audit through consideration of the international auditing and accounting standards and professional best practice IS audit frameworks. A review of the international financial reporting framework is undertaken to identify those auditing and accounting standards with medium or high impact upon IS audit practice. The identified auditing and accounting standards are then evaluated with senior IS audit practitioners in Australia and Canada. These auditing and accounting standards are subsequently mapped to the ITAF IT assurance processes to develop a benchmark model of financial IS audit in terms of the COBIT IT process domains. The implications of the benchmark model for the theory and practice of financial IS audit are then provided in Section 64.4.

64.3.1 Identified Auditing and Accounting Standards with Medium or High Impact

Two expert members of the research team reviewed the auditing and accounting standards to identify those standards with medium or high impact upon IS audit practice.

64.3.1.1 International Auditing Standards with Medium or High Impact upon IS Audit

The requirements of the auditing standards represent the core components of the auditing standards (Dennis, 2010). The requirements were examined to identify the components of the ISA with important implications for IS audit practice.

TABLE 64.1 International Standards on Auditing Identified as Having Medium or High Impact upon IS Audit Practice

Reference	International Standard on Auditing	Impact
ISA 240	The auditor's responsibilities relating to fraud in an audit of financial statements	Medium
ISA 315	Identifying and assessing the risks of material misstatement through understanding the entity and its environment	High
ISA 320	Materiality in planning and performing an audit	High
ISA 330	The auditor's procedures in response to assessed risks	Medium

An auditing standard was considered to directly affect IS audit practice where specific IT-related requirements to be addressed by auditors were stated. The identification of an auditing standard with important implications for IS audit practice required a direct reference to IS audit practice or the strong implication of a required IS audit procedure. The examples provided in ISACA (2008a) provided a guideline in this assessment.

The requirements of each auditing standard were coded by an expert member of the research team to identify the requirement's implications for IS audit practice. Each requirement was coded as having no, medium, or high impact upon IS audit practice. A second expert member of the research team reviewed this coding. A revised coding of the requirements of the auditing standards was then established and agreed by the research team. Table 64.1 identifies the ISA with medium and high impact upon IS audit practice as a result of this coding approach.

This expert assessment highlights the lack of specific requirements for IS audit practice arising from the international auditing standards. The next section provides the results of a similar assessment in the context of accounting standards.

64.3.1.2 International Accounting Standards with Medium or High Impact upon IS Audit

As with the requirements identified in the international auditing standards, the main principles of the international accounting standards represent the core components of the standards (Howieson and Langfield-Smith, 2003). The main principles of the accounting standards were examined to identify the components with important implications for IS audit practice.

The main principles for each accounting standard were coded by an expert member of the research team to identify each principle's implications for common IS audit practice. Each main principle was coded as having no, medium, or high impact upon IS audit practice. This coding was informed by the assessment of De George et al. (2010) that identified A-IFRS that significantly increased financial audit effort and complexity, while having regard for the indirect nature between accounting standards and IS audit practice.

A second expert member of the research team reviewed this coding. The revised coding of the main principles of the auditing standards was then established and agreed by the research team. Table 64.2 identifies the IAS and IFRS with medium and high impact upon IS audit practice as a result of this coding approach.

The assessment, as expected given the indirect relationship between accounting standards and IS audit practice, does not identify any accounting standards with "high" impact.

64.3.2 Evaluation of Auditing and Accounting Standards with High Impact upon IS Audit

A high-level summary of the international auditing and accounting standards identified as having medium or high impact upon IS audit was evaluated through semistructured interviews undertaken

TABLE 64.2 International Accounting Standards and International Financial Reporting Standards Identified as Having Medium or High Impact upon IS Audit Practice

Reference	International Accounting Standard/ International Financial Reporting Standard	Impact
IAS 19	Employee benefits	Medium
IAS 32	Financial instruments: presentation	Medium
IAS 36	Impairment of assets	Medium
IAS 38	Intangible assets	Medium
IAS 39	Financial instruments: recognition and measurement	Medium
IFRS 2	Share-based payment	Medium

with a purposive sample of public sector auditors. This approach evaluated the expert coding of the auditing and accounting standards from the audit practitioner perspective and provided a robust assessment of the impact of auditing and accounting standards upon IS audit practice.

The sample was obtained through the sponsorship of the Australian Research Council and members of the Australian Council of Auditors General. The sample included senior auditors from Australia and Canada at five different public sector audit offices. Altogether, 27 IS and financial auditors were interviewed to evaluate the expert coding of the auditing and accounting standards as outlined in Section 64.3.1. This approach ensured a diversity of opinion, industry experience, and regulatory frameworks in the sample. Table 64.3 provides basic demographic information for the auditors interviewed.

Each auditor was interviewed separately. A semistructured interview protocol was developed to guide the interviews to ensure the purpose of this research activity was addressed. The questions were designed to elicit clear and unambiguous responses from interviewees in the manner of Lillis (1999). The protocol requested each interviewee to agree or disagree with the expert coding of each auditing and accounting standard's impact. The interview protocol mapped the identified international auditing and accounting standards to their local Australian or Canadian equivalent. Each participant identified additional auditing and accounting standards with important implications for IS audit practice where possible.*

Interviews were recorded and transcribed verbatim for analysis. Interview transcripts were coded by individual sentence blocks into themes and concepts by a member of the research team to create a cross-case analytical matrix as set out by Lillis (1999).

Table 64.4 provides the results of this evaluation for auditing standards. Interviewees indicated common support for all auditing standards identified by the expert coding process as having medium or

TABLE 64.3 Demographic Attributes of Auditors Interviewed to Evaluate the Expert Coding of the Impact of Auditing and Accounting Standards upon Financial IS Audit Practice

Office	Interviewees	Average Experience (years)	Minimum (years)	Maximum (years)	Standard Deviation (years)
Australia	18 financial auditors 6 IS auditors	14.8	3	33	11.2
Canada	2 financial auditors 1 IS auditor	19	12	30	9.6
All audit offices	20 financial auditors 7 IS auditors	15.3	3	33	10.9

* The full interview protocol is available from the authors upon request.

TABLE 64.4 Results of the Evaluation of the Expert Coding of the International Standards on Auditing as Having "Medium" or "High" Impact as Set Out in Table 64.1

Reference	International Standard on Auditing	Agree ($n = 27$)	Disagree ($n = 27$)	Common Support
ISA 240	The auditor's responsibilities relating to fraud in an audit of financial statements	24	5	Yes
ISA 315	Identifying and assessing the risks of material misstatement through understanding the entity and its environment	24	3	Yes
ISA 320	Materiality in planning and performing an audit	21	7	Yes
ISA 330	The auditor's procedures in response to assessed risks	22	3	Yes

Note: Interviewees may make ambiguous or conflicting statements and so a single interviewee may indicate both agreement and disagreement with the same expert assessment.

TABLE 64.5 Results of the Evaluation of the Expert Coding of the International Accounting Standards and International Financial Reporting Standards as Having "Medium" or "High" Impact as Set Out in Table 64.2

Reference	International Accounting Standard/ International Financial Reporting Standard	Agree ($n = 27$)	Disagree ($n = 27$)	Common Support
IAS 19	Employee benefits	23	19	Yes
IAS 32	Financial instruments: presentation	23	17	Yes
IAS 36	Impairment of assets	24	18	Yes
IAS 38	Intangible assets	20	21	No
IAS 39	Financial instruments: recognition and measurement	22	17	Yes
IFRS 2	Share-based payment	18	23	No

Note: Interviewees may make ambiguous or conflicting statements and so a single interviewee may indicate both agreement and disagreement with the same expert assessment.

high impact upon IS audit practice. The interviewees did not identify auditing standards in addition to those identified by the expert coding process.

Table 64.5 similarly provides the results of this evaluation for accounting standards.

Interviewees consistently agreed that the auditing standards identified during the expert coding process had important implications for IS audit practice. In evaluating the assessment of the expert coding of the international accounting standards, the interviewees were more equivocal regarding the relationship between accounting standards and financial IS audit practice. The results of this research indicate the relationship between accounting standards and financial IS audit practice is more limited and indirect than the relationship between auditing standards and financial IS audit practice.

64.3.3 Financial IS Audit Benchmark Model

As outlined previously, the ITAF (ISACA, 2008b) provides a framework for IT assurance activities in support of diverse purposes, including but not limited to financial IS audit (Muthukrishnan, 2008). Singleton (2010) mapped the ITAF to identify the minimum IT controls to assess in a financial audit. The identification of international auditing and accounting standards with medium or high impact

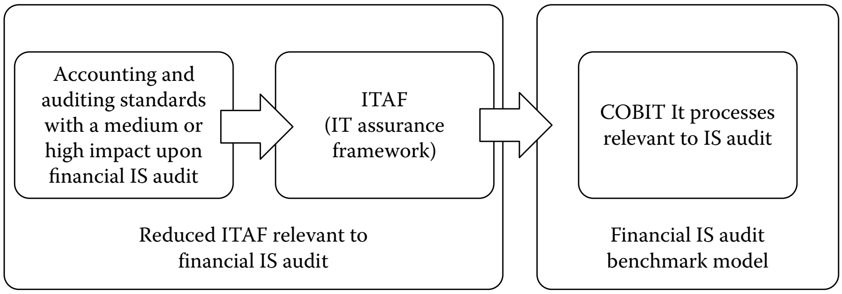

FIGURE 64.1 Process of mapping from the identified accounting and auditing standards with a medium or high impact upon financial IS audit to develop a financial IS audit benchmark model.

upon IS audit practice allows the refinement of this approach to develop a benchmark model of financial IS audit practice. This benchmark model is developed by relating the auditing and accounting standards having an impact upon IS audit with individual ITAF guidelines.

A research assistant experienced in financial IS audit mapped the identified IT-related components of the auditing and accounting standards to the ITAF guidelines. This mapping process was informed by the analysis presented in Singleton (2010). The research team reviewed the map developed by this process. As ITAF identifies the COBIT 4.1 processes related to each guideline, the map provides a basis for the development of the benchmark model for financial IS audit. Figure 64.1 illustrates the process for the development of the benchmark model.

The reduced ITAF financial IS audit benchmark model is presented in Table 64.6. By way of note, the mapping process did not identify any relationship between ITAF guidelines and accounting standards.

The steps of these IS audit methods directly relate to COBIT processes. The reduced ITAF as set out in Table 64.6 identifies the COBIT processes relating to each ITAF guideline. The development of a graphical representation of an IS audit benchmark model using ITAF's mapping to COBIT as a basis is therefore possible. This graphical representation of the financial IS audit benchmark model is provided in Figure 64.2.

As multiple COBIT IT processes support each ITAF guideline, the reduced ITAF implies 213 IT assurance activities in the benchmark model. In this context, an IT assurance activity is the consideration of an IT process in relation to an ITAF guideline. Figure 64.2 thus identifies the relative proportion of COBIT IT process domains on the basis of this map to indicate the relative emphasis of IS audit activity implied by the ITAF. Figure 64.2 presents the financial IS audit benchmark model at a high level by summarizing and aggregating the detail presented in Table 64.6.

In overall terms, the benchmark model provides an indication of the relative proportion of the assurance activities IS auditors "should" be undertaking to support the financial audit in the context of the international financial reporting framework and COBIT 4.1 process domains. The benchmark model prescribes that, in a financial IS audit, auditors should be giving the majority of their attention to "deliver and support" processes (40%) while approximately a quarter of their attention should be devoted to processes in the "planning and organizing" and "acquire and implement" areas each. Finally, "monitor and evaluate" processes should be reviewed but to a smaller extent (12%).

Table 64.7 indicates the specific relative emphasis of the assurance activities of the financial IS audit benchmark model in relation to COBIT 4.1 processes.

The detailed information presented in Table 64.7 allows IS auditors to gauge the relative emphasis of the assurance activities implied by the financial IS audit benchmark model. Taken together, Figure 64.2 and Table 64.7 provide a financial IS audit benchmark model that allows assessment of the alignment of financial IS audit methodologies in use with the international financial reporting framework. In assessing this alignment, it is important to understand that the procedures of audit methodologies do not directly equate to the processes and guidelines of the benchmark model. Each audit methodology procedure is likely to address multiple COBIT 4.1 processes.

TABLE 64.6 Reduced ITAF Model Showing ITAF Guidelines Relating Directly to the Requirements of Those International Standards on Auditing Having a High Impact upon IS Audit Practice

ITAF Guideline	Requirements of International Standard on Auditing (Application and Other Explanatory Material)	Relevant COBIT 4.1 IT Processes
3200 ENTERPRISE TOPICS		
3210 Implication of Enterprise-Wide Policies, Practices, and Standards on the IT Function		
Administrative; Management; Governance	IAS 315 (12) A42–A65	ME2
3230 Implication of Enterprise-Wide Assurance Initiatives on the IT Function

64.4 Discussion of Results and Implications for Theory and Practice

This section discusses the results of the research presented in this chapter, and identifies implications of these findings for IS audit theory and practice. These implications inform the discussion presented in Section 64.5.

64.4.1 Discussion of Results

The review of auditing and accounting standards was undertaken with the purpose of supporting the development of a financial IS audit benchmark model. Four ISA (ISA 240, ISA 315, ISA 320, and ISA 330) were identified as having a medium or high impact upon IS audit practice, and the interviewees in this study provided apparent support for the results of this review. These results highlight that the ISA lack specific requirements for IS audit practice.

The relationship between financial IS audit and ISA is stronger than the indirect relationship identified between financial IS audit and the international accounting standards. Although six international accounting standards (IAS 19, IAS 32, IAS 36, IAS 38, IAS 39, and IFRS 2) were identified by expert review as having a medium impact upon financial IS audit practice, the interviewees provided apparent but equivocal support for IAS 19, IAS 32, IAS 36, and IAS 39 only as indicated in Table 64.5. The interviewees participating in this study considered the relationship between accounting standards and financial IS audit practice as limited and indirect.

Relating the international audit and accounting standards to the ITAF in order to identify a reduced ITAF relevant to financial IS audit supports the observation that auditing standards provide limited direct guidance to financial IS audit whereas accounting standards provide limited and indirect guidance. In fact, Table 64.6 indicates that the strongest relationship between the ISA and audit practice exists for ISA 315 paragraph 21, which requires the financial auditor to come to an understanding of the entity's IS.

64.4.2 Implications for IS Audit Theory and Practice

In broad theoretic terms, the financial IS audit benchmark model presented in this chapter considers that the emphasis, or relative audit effort, of financial IS audit methodologies complying with the international financial reporting framework will align with the assurance activity emphasis identified in Figure 64.2 and Table 64.7. The benchmark model presents a relationship between the international reporting framework and IS audit practice. Future research is required to further explore the implications of this theoretical relationship as outlined later.

The results indicate that IS auditors in practice must look to professional guidelines and best practice frameworks such as COBIT 4.1 and the ITAF to develop IS audit methods that address the requirements of the auditing standards. However, both COBIT 4.1 and the ITAF support a wide range of IS audit engagements, not just financial IS audit engagements.

This chapter has developed a benchmark model for financial IS audit by reducing the scope of the ITAF through relating the audit and accounting standards to the ITAF guidelines. The benchmark model provides guidance to auditors seeking to assess the alignment of the financial IS audit methodologies in use with the international financial reporting framework, and additionally guides the development of IS audit methodologies in the financial audit context. Indeed, the benchmark model of Figure 64.2 prescribes that, in a financial IS audit, auditors should be giving the majority of their attention to "deliver and support" processes (40%) while approximately a quarter of their attention should be devoted to processes in the "planning and organizing" and "acquire and implement" areas each. Finally, "monitor and evaluate" processes should be reviewed but to a smaller extent (12%).

64.5 Conclusions, Limitations, and Future Research

This chapter reviewed the international audit and accounting standards increasingly adopted either in whole or as country-specific equivalents by many countries in furtherance of the goal of international harmonization of the financial reporting framework. A detailed analysis of the audit and accounting standards with medium and high impact upon IS audit practice was undertaken and evaluated with public sector auditors, and a financial IS audit benchmark model subsequently developed.

The findings indicate the audit and accounting standards with a medium or high impact upon IS audit practice. The conclusion is that auditing standards have a direct relationship with IS audit practice. The limited number of auditing standards identified in this chapter highlights the absence of auditing standard requirements with important and specific implications for IS audit practice. Further, the relationship between accounting standards and IS audit practice was found to be limited and indirect. This chapter also identifies a benchmark model for financial IS audit that provides for assessment of the alignment of the financial IS audit methodologies in use with the international financial reporting framework, and guides the development of future IS audit methods.

The research has limitations. The benchmark model developed is exploratory, and the evaluation of the assessment of the international audit and accounting standards is limited to senior auditors practicing in Australia and Canada. Both Australia and Canada have similar audit traditions and regulatory frameworks in place. The benchmark model does not consider guidelines and practice requirements other than the international financial reporting framework, and it is apparent that "best practice" resources are widely used in the development of financial IS audit methodologies. Additionally, the evaluation of the expert review sought feedback only from public sector auditors, and thus application of the benchmark model to financial IS audit in private practice may require caution. Nevertheless, the use of a purposive sample with senior auditors from two countries strengthens the representativeness of the sample and the likely applicability to the wider audit profession of the benchmark model developed.

Future research may seek to address the limitations of the analysis presented in this chapter by evaluating the expert review with private sector auditors. Future research assessing financial IS audit practice in comparison with the benchmark model is required to ascertain the extent current practice is in alignment with the international financial reporting framework. Such research also provides an opportunity to consider the robustness of the benchmark model of financial IS audit developed in this chapter. Finally, future refinement of the benchmark model to incorporate "best practice" IS audit resources other than the international financial reporting framework may also yield a more robust benchmark model for financial IS audit as well as for other types of IS audit such as the IT-focused, operational, or regulatory audits identified by Muthukrishnan (2008).

The international harmonization of audit and accounting standards has significant implications for financial IS audit practice. The financial IS audit benchmark model developed in this chapter by reviewing the audit and accounting standards provides an opportunity for financial IS auditors to assess the IS audit approaches in use and to guide their future development. Overall, this chapter presents opportunities for future research in the area of IS audit as well as providing guidance to IS audit professionals looking to align financial IS audit effort with the requirements of the international financial reporting framework set out by the international audit and accounting standards.

Acknowledgments

The material presented in this chapter was supported under Australian Research Council's Linkage Projects funding scheme (Project Number LP0882068). The support of the Partner Organizations CPA Australia, the Institute of Chartered Accountants in Australia, and the Tasmanian Audit Office for this research project is also acknowledged. The authors also gratefully acknowledge the research assistance of Lynne Gerke and Agung Muliawan in the collection and summarization of some of the data for this project.

Information Systems and the Domain of Business Intertwined

65

Strategic Alignment Maturity

Jerry Luftman
Global Institute for IT Management

65.1 Introduction

Business–information technology (IT) alignment refers to applying IT in an appropriate and timely way, in harmony with business strategies, goals, and needs. It has been a fundamental concern of business and IT executives since the 1970s. This definition of alignment addresses:

- How IT is aligned with the business
- How the business should or could be aligned with IT

Mature alignment evolves into a relationship in which IT and other business functions adapt their strategies together. When discussing business–IT alignment, terms such as harmony, linkage, fusion, converged, and integration are frequently used synonymously with the term alignment. It does not matter whether one considers alignment from either a business-driven perspective (IT enabled) or from an IT-driven perspective; the objective is to ensure that the organizational strategies adapt harmoniously. The evidence that IT has the power to transform whole industries and markets is strong.[1–10] In addition to research that will be discussed in this chapter, good examples that have been discussed previously include Amazon.com, Dell, Cisco, and Federal Express. Important questions that need to be addressed include the following:

- How can organizations assess alignment?
- How can organizations improve alignment?
- How can organizations achieve mature alignment?

The purpose of this chapter is to present an approach for assessing the maturity of a firm's business–IT alignment. Until recently, nothing has been available. The alignment maturity assessment described in

this chapter provides a comprehensive descriptive and prescriptive vehicle for organizations to evaluate business–IT alignment in terms of where they are and what they can do to improve the alignment. The maturity assessment applies the previous research that identified enablers/inhibitors to achieving alignment[10,11] and the empirical evidence gathered by management consultants who applied the methodology that leverages the most important enablers and inhibitors as building blocks for the evaluation. The foundation for the maturity assessment is also based on the popular work done by the Software Engineering Institute, Keen's "reach and range," and an evolution of the Nolan and Gibson stages of growth.[12–14]

65.2 Why Alignment Is Important

Alignment's importance has been well known and well documented since the late 1970s.[10,15–23] Over the years, it has persisted among the top-ranked concerns of business executives. IT and business alignment was the second highest ranked issue in the recent trends survey of IT leaders from 362 global organizations.[24] Alignment seems more important as companies strive to integrate technology and business in light of dynamic business strategies and the continuously evolving technologies.[2,25] In addition to the importance of alignment, what has not been clear is how to achieve and sustain this harmony between business and IT, how to assess the maturity of alignment, and what the impact of misalignment might be on the firm.[26] To achieve and sustain this synergistic relationship is anything but easy.

There are several reasons why attaining IT–business alignment has been so elusive.

The first reason is that the definition of alignment is frequently focused only on how IT is aligned (e.g., converged, in harmony, integrated, linked, synchronized) with the business. Alignment must also address how the business is aligned with IT. Alignment must focus on how IT and the business are aligned with each other; IT can both enable and drive business change.

The second reason is that organizations (practitioners, consultants, academics) have often looked for a silver bullet. Originally, some thought the right technology (e.g., infrastructure, applications) was the answer. While important, it is not enough. Likewise, improved communications between IT and the business help, but it is not enough. Similarly, establishing a partnership is not enough nor is balanced metrics that combine appropriate business and technical measurements. Clearly, mature alignment cannot be attained without effective and efficient execution and demonstration of value, but this alone is also insufficient. More recently, governance has been touted as the answer—to identify and prioritize projects, resources, and risks. Today, we also recognize the importance of having the appropriate skills to execute and support the environment. Our research has found that all six of these components must be addressed to improve alignment.

The third reason that IT–business alignment has been elusive is that there has not been an effective tool to gauge the maturity of IT–business alignment—a tool that can provide both a descriptive assessment and a prescriptive roadmap on how to improve. As you will see, the insights from the alignment maturity benchmarking provide extensive insights to this longstanding conundrum.

The fourth reason that IT–business alignment has been so difficult to achieve is that there is a tendency in many organizations (even ones where the importance of alignment is recognized) to focus their attention on IT infrastructure considerations. This unbalanced approach can often lead to missed opportunities to identify elements of the business infrastructure that are in need of improvements.

Finally, the fifth reason that the advancement of IT–business alignment has been stalled involves semantic differences in how to refer to it. Disagreements regarding alignment terminology ("linked" vs. "converged"; "integrated" vs. "harmonized") have ironically become a barrier to alignment itself.

Luftman's research suggests that while there is no silver bullet for achieving alignment, progress has been made. In fact, the research demonstrates that "a line" has been drawn. When organizations

cross it, they have identified and addressed ways to enhance IT–business alignment. The alignment maturity model is thus both descriptive and prescriptive. CIO's can use it to identify their organization's alignment maturity and identify means to enhance it. Yet, that "line" is dynamic and continually evolving. So alignment can always be improved.

From measuring the six components in organizations in the United States, Latin America, Europe, and India, we found that most organizations today are in Level 3 of a five-level maturity assessment model. Hence, the pronouncement of the "death of alignment" is premature; there is still a long way to go in the journey for aligning IT and business.

Identifying an organization's alignment maturity provides an excellent vehicle for understanding and improving the business–IT alignment. As elaborated on in this chapter, alignment maturity focuses on six important areas. ALL must be simultaneously addressed to improve the harmony among IT and business. Too frequently, consultants and practitioners, looking for the silver bullet, focused their attention on only one or a subset of these important considerations. As companies strive to link technology and business, they must address both

- Doing the right things (effectiveness)
- Doing things right (efficiency)[2,10,25]

In recent years, a great deal of research and analysis focused on the linkages among business and IT,[2,3,10,11,27] the role of partnerships among IT and business management,[13,27] and the need to understand the transformation of business strategies resulting from the competitive use of IT.[28,29] Firms need to change not only their business scope, but also their infrastructure as a result of IT innovation.[30–32] Much of this research, however, was conceptual. Empirical studies of alignment[23,33,34] only examined a single industry and/or firm. Conclusions from such empirical studies are potentially biased and may not be applicable to other industries. These studies lacked the consistent results across industries, across functional positions, and across time. This provided the impetus for defining a vehicle for assessing business, along with providing a roadmap for how best to improve it: IT alignment maturity.

As discussed earlier, alignment maturity evolves into a relationship in which the function of IT and other business functions adapt their strategies together. Achieving alignment is evolutionary and dynamic. IT requires strong support from senior management, good working relationships, strong leadership, appropriate prioritization, trust, and effective communication, as well as a thorough understanding of the business and technical environments. Achieving and sustaining alignment demands focusing on maximizing the enablers and minimizing the inhibitors that cultivate the integration of IT and business.

Alignment of IT strategy and the organization's business strategy is a fundamental principle advocated for several decades.[8,35,36] IT investment has been increasing since its inception, as managers look for ways to manage IT successfully and to integrate it into the organization's strategies. As a result, IT managers need to

- Be knowledgeable about how the new IT technologies can be integrated into the business and with existing/emerging technologies
- Be privy to senior management's tactical and strategic plans
- Be present when corporate strategies are discussed
- Understand the strengths and weaknesses of the technologies in question and the corporate-wide implications[36]

Several proposed frameworks assess the strategic issues of IT as a competitive weapon. They have not, however, yielded empirical evidence, nor have they provided a roadmap to assess and enhance alignment. Numerous studies focus on business process redesign and reengineering as a way to achieve competitive advantage with IT.[37–40] This advantage comes from the appropriate application of IT as a driver and enabler of business strategies.

65.3 Strategic Alignment Maturity

The concept of alignment *maturity* as a necessary precondition for an organization's ability to implement its strategy emerged as a concept in the late 1990s as it became increasingly evident that organizations were, by and large, failing to successfully execute nominally well-defined strategic objectives. Why was this the case? Early research into this issue[41] hypothesized that an organization's ability to successfully implement strategy was related to the "level" of strategic alignment between IT and the business, which reflects both the dynamic nature of alignment and the fact that alignment is, itself, a *process* that reflects key organizational practices that enable (or inhibit, in their absence or misapplication) alignment.[10,41] A model of alignment maturity emerged from this research that reflects these concepts. As Figure 65.1 illustrates, the *Strategic Alignment Maturity* (SAM) model involves the following five conceptual levels of SAM:

1. Initial/ad hoc process—Business and IT are not aligned or harmonized
2. Committed process—The organization has committed to becoming aligned
3. Established focused process—SAM established and focused on business objectives
4. Improved/managed process—Reinforcing the concept of IT as a "value center"
5. Optimized process—Integrated and coadaptive business and IT strategic planning

Each of the five levels of alignment maturity focuses, in turn, on a set of six components based on practices validated in 2001 with an evaluation of 25 "*Fortune 500*" companies. As of the writing of this chapter, 362 Global 1000 organizations from around the world (and several hundred smaller companies) and 2100 business and IT executives have participated in formally assessing their IT business alignment maturity. Some of the insights from these assessments are discussed in the section of this chapter that describes the different maturity components. Assessments continue to be performed.

FIGURE 65.1 Alignment maturity summary.

As discussed earlier, organizations have often looked for a silver bullet to improve the alignment of IT–business. Some thought the right technology (e.g., infrastructure, applications) was the answer. While important, it is not enough. Likewise, improved communications between IT and the business help, but are not enough. Similarly, establishing a partnership is not enough, nor is balanced metrics that combine appropriate business and technical measurements. More recently, governance has been touted as the answer—to identify and prioritize projects, resources, and risks. Today, we also recognize the importance of having the appropriate skills to execute and support the environment. Research has found that all six of these components must be addressed to improve alignment.

Additionally, there has not been an effective tool to gauge the maturity of the IT–business alignment—a tool that can provide both a descriptive assessment and a prescriptive roadmap on how to improve. From measuring the six components in organizations in the United States, Latin America, Europe, and India, most organizations today are in a low Level 3 of a five-level maturity assessment model; there are still many opportunities for improvement.

The six IT–business alignment criteria are illustrated in Figure 65.2 and are described at a more detailed level in the following section. All six must be addressed to ensure mature alignment; looking for a single answer will just not do it. These six criteria are

1. *Communications maturity*—Ensuring effective ongoing knowledge sharing across organizations
2. *Competency/value measurement maturity*—Demonstrating the value of IT in terms of contribution to the business
3. *Governance maturity*—Ensuring that the appropriate business and IT participants formally discuss and review the priorities and allocations of IT resources

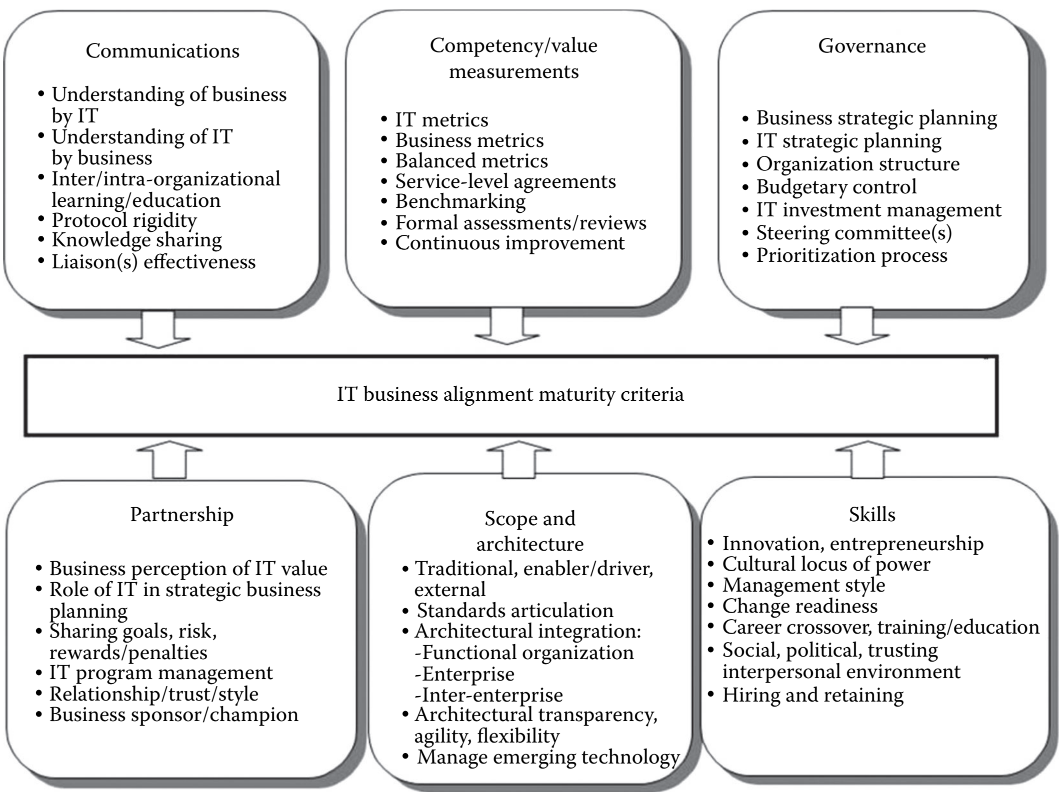

FIGURE 65.2 Alignment maturity criteria.

4. *Partnership maturity*—How each organization perceives the contribution of the other, the trust that develops among the participants, and the sharing of risks and rewards
5. *Scope and architecture maturity*—The extent to which IT is able to
   - Go beyond the back office and into the front office of the organization to directly impact customers/clients and strategic partners
   - Assume a role supporting a flexible infrastructure that is transparent to all business partners and customers
   - Evaluate and apply emerging technologies effectively
   - Enable or drive business processes and strategies as a true standard
   - Provide solutions customizable to customer needs
6. *Skills maturity*—Human resource considerations such as training, salary, performance feedback, and career opportunities are assessed to identify how to enhance the organization's cultural and social environment as a component of organizational effectiveness

Knowing the maturity of its strategic choices and alignment practices makes it possible for a firm to see where it stands with respect to its "alignment gaps" and how it can close these gaps. The pyramid in Figure 65.3 illustrates the alignment gap on each level of alignment maturity vividly. The five levels of alignment maturity are introduced in this section and then will be elaborated in the following section.

Level 1: Initial or ad hoc processes. Organizations at Level 1 generally have poor communications between IT and the business and also a poor understanding of the value or contribution the other provides. Their relationships tend to be formal and rigid, and their metrics are usually technical rather than business oriented. Service-level agreements (SLAs) tend to be sporadic. IT planning or business planning is ad hoc. IT is viewed as a cost center and considered "a cost of doing business." The two parties also have minimal trust and partnership. IT projects rarely have business sponsors or champions. The business and IT also have little to no career crossovers. Applications focus on traditional back-office support, such as e-mail, accounting, and HR, with no integration among them. Finally, Level 1 organizations do not have an aligned IT–business strategy.

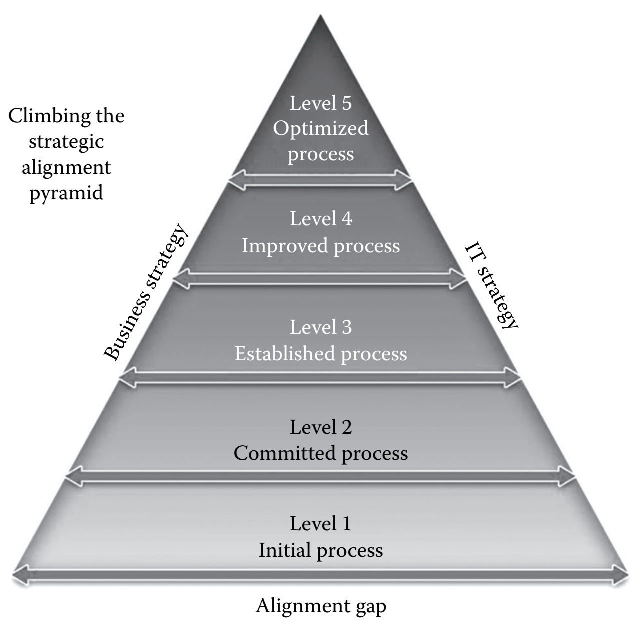

FIGURE 65.3 Alignment gaps.

Level 2: Committed processes. Organizations at Level 2 have begun enhancing their IT–business relationship. Alignment tends to focus on functions or departments (e.g., finance, R&D, manufacturing, marketing) or geographic locations (e.g., United States, Europe, Asia). The business and IT have a limited understanding of each other's responsibilities and roles. IT metrics and service levels are technical and cost-oriented, and they are not linked to business metrics. Few continuous improvement programs exist. Management interactions between IT and the business tend to be transaction-based rather than partnership-based, and IT spending relates to basic operations. Business sponsorship of IT projects is limited. At the function level, there is some career crossover between the business and IT. IT management considers technical skills the most important for IT.

Level 3: Established, focused processes. In Level 3 organizations, IT assets become more integrated enterprise-wide. Senior and mid-level IT management understand the business, and the business's understanding of IT is emerging. SLAs begin to emerge across shared or acted upon. Strategic planning tends to be done at the business unit level, although some inter-organizational planning has begun. IT is increasingly viewed by the business as an asset, but project prioritization still usually responds to "the loudest voice." Formal IT steering committees emerge and meet regularly. IT spending tends to be controlled by budgets, and IT is still seen as a cost center. But awareness of IT's "investment potential" is emerging. The business is more tolerant of risk and is willing to share some risk with IT. At the function level, the business sponsors IT projects and career crossovers between business and IT occur. Both business and technical skills are important to business and IT managers. Technology standards and architecture have emerged at both the enterprise level and with key external partners.

Level 4: Improved, managed processes. Organizations at Level 4 manage the processes they need for strategic alignment within the enterprise. One of the important attributes of this level is that the gap has closed between IT understanding the business and the business understanding IT. As a result, Level 4 organizations have effective decision making and IT provides services that reinforce the concept of IT as a value center. Level 4 organizations leverage their IT assets enterprise-wide, and they focus applications on enhancing business processes for sustainable competitive advantage. SLAs are also enterprise-wide, and benchmarking is a routine practice. Strategic business and IT planning processes are managed across the enterprise. Formal IT steering committees meet regularly and are effective at the strategic, tactical, and operational levels. The business views IT as a valued service provider and as an enabler (or driver) of change. In fact, the business shares risks and rewards with IT by providing effective sponsorship and championing all IT projects. Overall, change management is highly effective. Career crossovers between business and IT occur across functions, with business and technical skills recognized as very important to the business and IT.

Level 5: Optimized processes. Organizations at Level 5 have optimized strategic IT–business alignment through rigorous governance processes that integrate strategic business planning and IT planning. Alignment goes beyond the enterprise by leveraging IT with the company's business partners, customers, and clients, as well. IT has extended its reach to encompass the value chains of external customers and suppliers. Relationships between the business and IT are informal, and knowledge is shared with external partners. Business metrics, IT metrics, and SLAs also extend to external partners, and benchmarking is routinely performed with these partners. Strategic business and IT planning are integrated across the organization, as well as outside the organization.

Figure 65.4 summarizes the results of the 362 Global 1000 companies that have gone through the assessment to date. It illustrates where there is relative agreement regarding which areas are strong and which are weak, and it identifies the gaps between business and IT executive's opinions. The *Y*-axis represents the five levels of maturity; the *X*-axis expands each of the six components of maturity. The maturity elements highlighted in bold tend to be assessed as the strongest, while the italicized elements are those that are assessed as the lowest (hence the areas least aligned). Note that within each of the six components there are diamond lines representing the assessments from IT executives, and circle lines showing the corresponding assessments from business executives. The areas where the circle and

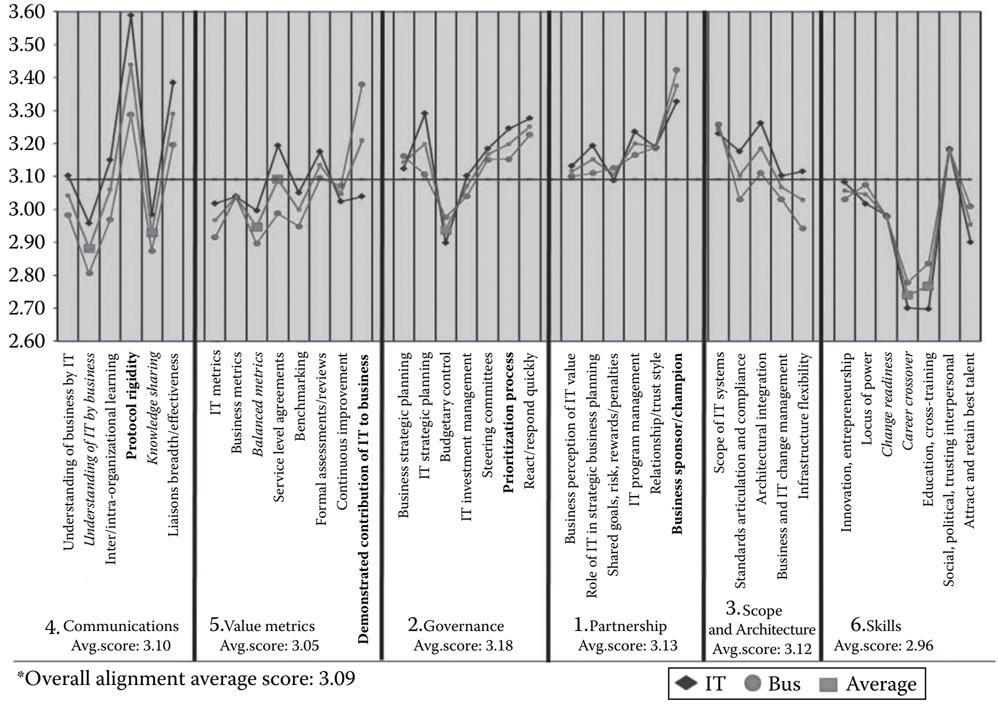

FIGURE 65.4 Overall SAM assessment maturity.

diamond lines converge or overlap depict areas where there is the most agreement (and thus synergy) between business and IT. Conversely, areas with large gaps between the circle and diamond lines are the ones that show disagreement among IT and business executives; these are area that need to be reconciled. For example, Figure 65.4 illustrates a tighter synergy between business and IT in the areas of partnership and skills than for communications. The major elements will be discussed later.

Figure 65.5 summarizes these results by region. A general trend that Figure 65.5 illustrates is that across most components, Asian organizations have higher maturity scores (denoted by circle lines), followed by American and Latin American organizations (denoted by triangle and large diamond lines, respectively), and then European organizations (denoted by small diamond lines). The pattern of maturity scores for Australian organizations (denoted by star lines) reveals that in some dimensions they score as high as or higher than Asian organizations, while for other dimensions they score lower than all other regions. (Since only one African organization is represented in the data, no trends for African organizations are assumed.)

With an overall average maturity score of 3.09, it is clear that there are still opportunities to improve the IT business relationship; alignment is not dead.

A similar graph may be used to plot the responses from an individual organization assessment to identify opportunities for improvement (using the assessment as a prescriptive tool) and to benchmark things such as how a specific organization compares to

- The overall average set of responses
- The responses from exemplar organizations
- Other organizations in their industry (finance, pharmaceutical, utility, retail, healthcare, education)
- Respondents from similar positions (e.g., CIO's, CEO's, CFO's) in other firms

Once the maturity level is understood, the assessment method provides the organization with a prescriptive roadmap that identifies opportunities for enhancing the harmonious relationship of business and IT. This alignment process is expanded in this chapter.

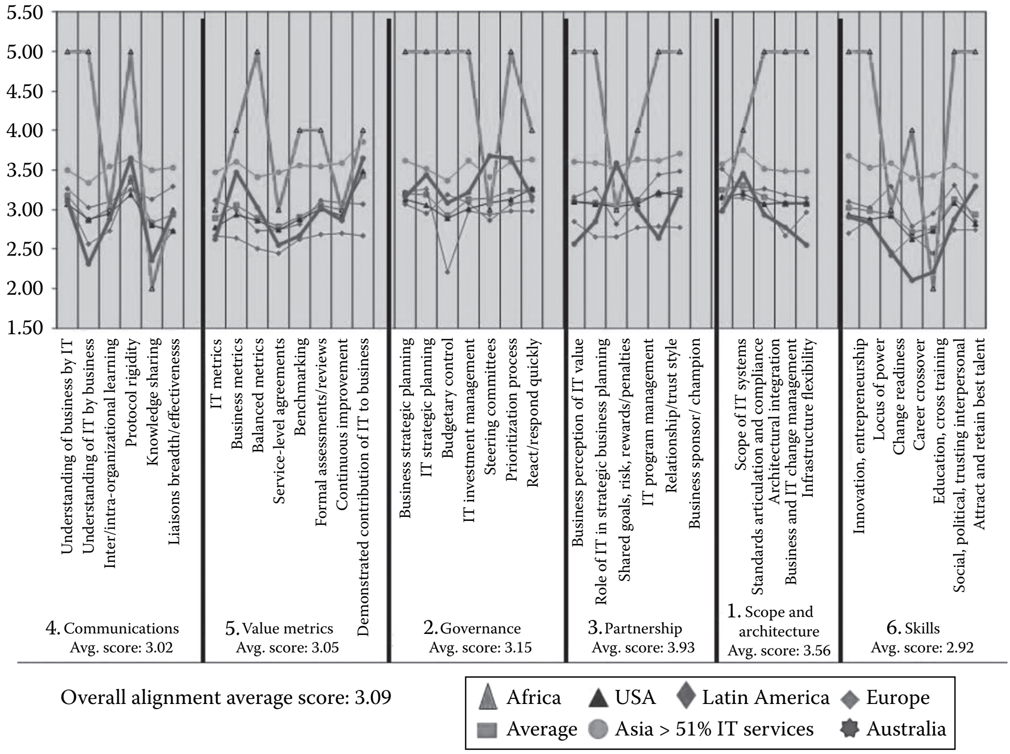

FIGURE 65.5 Geographic SAM summary.

65.4 Six Strategic Alignment Maturity Criteria

This section describes each of the six components (illustrated in Figure 65.2) that are evaluated in deriving the level of SAM. Examples taken from actual assessments illustrate the kinds of insights that can be identified. Most organizations today appear to be around Level 3, as illustrated in Figure 65.6.

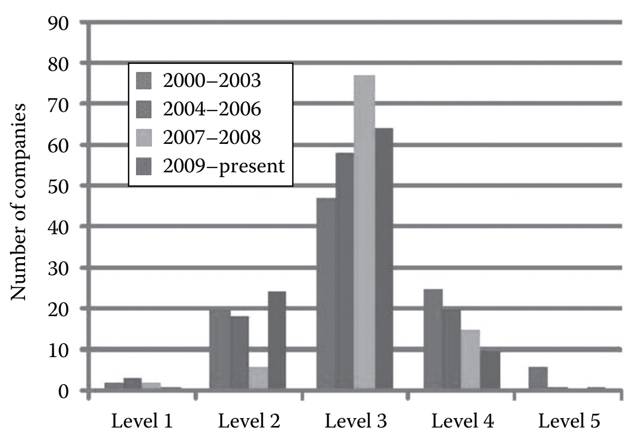

FIGURE 65.6 Distribution of SAM scores.

TABLE 65.1 Maturity Levels by Year

Years	Number of Companies	% of Companies in Level 1	% of Companies in Level 2	% of Companies in Level 3	% of Companies in Level 4	% of Companies in Level 5	Overall Average
2000–2003	83	2	20	47	25	6	2.99
2004–2006	99	3	18	58	20	1	3.06
2007–2008	64	2	6	77	15	0	3.11
2009–Present	116	1	24	64	10	1	3.19
Overall	362	1.25	12.92	56.67	27.92	1.25	3.17

Overall alignment average score: 3.09

That means that the average results from the 362 Global 1000 companies' formal assessments (and the several hundred additional informal assessments from multiple years of Society for Information Management surveys) to date are around Level 3. A gradual increase in the overall maturity level over the past decade can be observed in Table 65.1. The results are similar to what has been found by the Carnegie Software Engineering Institute development process model that assesses the comparable stages of application development maturity.

So, while IT business alignment seems to be improving, it is still a pervasive persistent challenge. Naturally, the objective of the SAM model is to identify opportunities to move the organization to a higher level (i.e., higher than Level 3) of SAM. Keep in mind that the primary objective of the assessment is not the maturity level used just as a descriptive tool of an organizations maturity; albeit it provides interesting benchmark comparisons. The primary objective of the assessment is to understand (as illustrated in Figures 65.4 and 65.5) where IT and business executives

- Agree that a criterion needs to be improved
- Agree that a criterion is good, but can be better
- Disagree with how good/bad a criterion is
- Desire to focus their efforts to improve

As illustrated in Figure 65.5, there were differences in the overall SAM alignment scores by region. On average, Asian organizations had higher scores than their American, Australian, and European counterparts. The SAM scores by criteria and by region are summarized in Table 65.2. It is valuable to benchmark organizations by geography as well as comparing alignment trends across the geographies. This will be discussed later.

When there is agreement among the participants regarding the criteria assessment, the model can be used as a prescriptive roadmap to identify how alignment maturity can be improved. However, when there is disagreement, the key stakeholders (i.e., any groups or individuals who can affect or are affected

TABLE 65.2 Geography Maturity by Component

Geography	Number of Companies	Communication	Competency	Governance	Partnership	Scope of IT Architecture	Skills	Overall Average
Europe	61	2.85	2.63	2.94	2.78	3.01	2.70	2.82
Australia	28	2.88	3.01	3.15	2.96	2.96	2.68	2.94
United States	184	2.93	2.93	3.07	3.09	3.12	2.84	3.00
Latin America	44	3.17	2.94	3.03	3.16	3.27	3.00	3.10
Asia	44	3.52	3.59	3.58	3.64	3.60	3.55	3.58
Africa	1	4.0	3.71	4.13	4.4	4.0	4.0	4.05

Overall alignment average score: 3.09

TABLE 65.3 Industry Maturity by Component

Industry Name	Number of Companies	Communications	Competency	Governance	Partnership	Tech. Scope	Skills	Overall Average
Retail	10	3.54	3.52	3.70	3.75	3.73	3.45	3.62
Hotel/ entertainment	10	3.23	3.39	3.38	3.49	3.77	3.35	3.44
Service	48	3.26	3.23	3.34	3.36	3.34	3.35	3.31
Insurance	11	3.19	3.34	3.51	3.31	3.34	2.89	3.26
Oil/Gas/Mining	13	3.05	3.31	3.36	3.06	3.37	2.98	3.19
Manufacturing	54	3.21	3.03	3.10	3.15	3.24	3.07	3.13
Financial	106	2.93	2.87	3.13	3.17	3.14	2.82	3.01
Utility	7	3.09	3.21	2.64	2.76	3.40	2.75	2.98
Pharmaceutical	15	2.95	2.77	2.98	2.89	3.00	2.97	2.93
HealthCare	18	2.94	2.85	3.02	2.97	3.04	2.73	2.92
Transportation	21	2.77	2.97	2.82	2.93	2.84	2.68	2.84
Government	9	2.91	2.54	3.03	2.99	2.86	2.49	2.80
Chemical	7	2.75	2.64	2.86	2.81	3.08	2.44	2.76
Telecommunication	11	2.68	2.68	2.94	2.69	3.03	2.44	2.74
Agriculture	11	2.54	2.61	3.13	2.63	2.50	2.41	2.64
Educational	11	2.66	2.46	2.83	2.53	2.72	2.56	2.63

Overall alignment average score: 3.09

by IT in the firm) need to understand the points of view of the participants and come to an agreement regarding the criteria and how to enhance it. The organization cannot identify an appropriate road to take if they cannot come to agreement regarding where they want to go. Once the group has identified an agreed to list of areas for improvement, they can proceed to use the model as a prescriptive roadmap. Hence, it is not the maturity "number" that is important. It is what the organization does as a result of identifying how they can work together to improve the alignment maturity.

The next six subsections discuss each of the SAM criteria in more detail and include examples of how they manifest themselves in organizations. These examples have been abstracted from recent research done with a number of major U.S. and global organizations.[11] Table 65.3 summarizes the data from this research across the six SAM components by industry. In terms of their alignment maturity, it is evident that industries can vary considerably in their overall scores. For example, the service sector outperformed the transportation sector by an overall score of 3.31–2.84, while the gap between the retail and educational sectors was almost a full point (3.62 vs. 2.63).

Since this research is still ongoing and the companies that have participated have been assured anonymity, it is not possible to share the specific names of the participating organizations. However, each section illustrates specific issues of SAM that have been uncovered in the research and identifies the industry of the participating organizations.

65.4.1 Communications

Effective exchange of ideas and a clear understanding of the key ideas that ensure successful strategies are high on the list of enablers and inhibitors to alignment. Too often, there is little business awareness on the part of IT or little IT appreciation on the part of the business. The 362 Global 1000 benchmark firm results indicate that 21% of the IT organizations either do not understand or have a limited understanding of business, while 39% of the business executives either do not understand or have a limited understanding of IT. Given the dynamic environment in which most organizations find themselves, ensuring ongoing knowledge sharing across organizations is paramount.

Many firms choose to employ people in formal interunit "liaison" roles or cross-functional teams to facilitate this knowledge sharing. The key word here is "*facilitate*." Some organizations have facilitators whose role is to serve as the sole conduit of interaction among the different units of the organization. This approach tends to stifle rather than foster effective communications. Rigid protocols that impede discussions and the sharing of ideas should be avoided. The 362 Global 1000 benchmark firm results indicate that 54% of the firms identify liaisons as a major opportunity for improvement.

For example, a large aerospace company assessed its communications alignment maturity at Level 2. Business–IT understanding is sporadic. The relationship between IT and the business function could be improved. Improving communication should focus on how to create the understanding of IT as a strategic business partner by the businesses it supports rather than simply a service provider. The firm's CIO made the comment that there is "no constructive partnership." However, in an interview with the firm's Director of Engineering and Infrastructure, he stated that he views his organization as a "strategic business partner." One way to improve communications and, more importantly, understanding would be to establish effective business function/IT liaisons that facilitate sharing of knowledge and ideas.

In a second case, a large financial services company's communication alignment maturity placed it in Level 2 with some attributes of Level 1. Business awareness within IT is through specialized IT business analysts, who understand and translate the business needs to other IT staff (i.e., there is limited awareness of business by general IT staff). Awareness of IT by the firm's business functions is also limited, although senior and mid-level management are aware of IT's potential. Communications are achieved through biweekly priority meetings of the senior and middle-level managers from both groups, where they discuss requirements, priorities, and IT implementation. But it is still a Level 2 because of the effectiveness of the interaction.

In a third example, a large utility company's communication alignment maturity places it at Level 2. Communications are not open until circumstances force the business to identify specific needs. There is a lack of trust and openness among some business units and their IT team. IT business partners tend to be bottlenecks in meeting commitments. IT's poor performance in previous years left scars that have not healed.

From a geographic perspective (as illustrated in Table 65.2), Asian organizations achieved the highest level of maturity in the communications component with an overall score of 3.52, followed by Latin America with a score of 3.17. The United States, Australia, and European scores were 2.93, 2.88, and 2.85, respectively.

65.4.2 Competency/Value Measurements

Too many IT organizations cannot demonstrate their value to the business in terms that the business understands. Frequently, business and IT metrics of value differ. A balanced "dashboard" that demonstrates the value of IT in terms of contribution to the business is needed. The 362 Global 1000 benchmark firm results indicate that two-thirds of the firms can improve this important area.

Service levels that assess IT's commitments to the business often help. However, the service levels have to be expressed in terms that the business understands and accepts. The service levels should be tied to criteria (see Section 65.4.4) that clearly define the rewards and penalties for surpassing or missing the objectives. The 362 Global 1000 benchmark firm results indicate that 63% of the firms can significantly improve their SLAs.

Frequently, organizations devote significant resources to measuring performance factors. However, they spend much less of their resources on taking actions based on these measurements. For example, an organization that requires analyzing ROI before a project begins, but then does not review how well objectives were met after the project was deployed provides little to the project's success. It is important to assess these criteria to understand (1) the factors that lead to missing the criteria and (2) what can be learned to improve the environment continuously.

For example, a large aerospace company assessed its competency/value measurement maturity to be at Level 2. IT operates as cost center. IT metrics are focused at the functional level, and SLAs are technical in nature. One area that could help to improve maturity would be to add more business-related metrics to SLAs to help form more of a partnership between IT and the business units. Periodic formal assessments and reviews in support of continuous improvement would also be beneficial.

A large software development company assessed its competency/value measurement maturity at Level 3. Established metrics evaluate the extent of service provided to the business functions. These metrics go beyond basic service availability and help desk responsiveness, evaluating such issues as end-user satisfaction and application development effectiveness. The metrics are consolidated on to an overall dashboard. However, because no formal feedback mechanisms are in place to react to a metric, the dashboard cannot be considered to be managed.

At a large financial services company, IT competency/value was assessed at Level 2 because the company uses cost-efficient methods within the business and functional organizations. Balanced metrics are emerging through linked business and IT metrics, and a balanced scorecard is provided to senior management. SLAs are technical at the functional level. Benchmarking is not generally practiced and is informal in the few areas where it is practiced. Formal assessments are done typically for problems and minimum measurements are taken after the assessment of failures.

Table 65.2 shows significantly different IT competency SAM scores across regions. Asian organizations lead the way with an overall score of 3.59, followed by Australian firms with a score of 3.01; Latin American firms (2.94) are followed closely by American firms (2.93). European organizations scored the lowest in this dimension, with a score of 2.63.

65.4.3 Governance

The considerations for IT governance were defined briefly in Figure 65.1. Ensuring that the appropriate business and IT participants formally discuss and review the priorities and allocation of IT resources is among the most important enablers/inhibitors of alignment. This decision-making authority needs to be clearly defined. The 362 Global 1000 benchmark firm results indicate that 57% of the firms should be improving this important component of alignment.

For example, IT governance in a large aerospace company is tactical at the core business level and not consistent across the enterprise. For this reason, they reported a Level 2 maturity assessment. IT can be characterized as reactive to CEO direction. Developing an integrated enterprise-wide strategic business plan for IT would facilitate better partnering within the firm and would lay the groundwork for external partnerships with customers and suppliers.

A large communications manufacturing company assessed its governance maturity at a level falling between 1 and 2. IT does little strategic planning because it operates as a cost center and, therefore, cost reduction is a key objective. In addition, priorities are reactive to business needs as business manager's request services.

A large computing services company assessed their governance maturity at Level 1+. A strategic planning committee meets twice a year. The committee consists of corporate top management with regional representation. Topics or results are neither discussed nor published to all employees. The reporting structure is federated with the CIO reporting to a COO. IT investments are traditionally made to support operations and maintenance. Regional or corporate sponsors are involved with some projects. Prioritization is occasionally responsive.

From a geographic perspective (as illustrated in Table 65.2), Asian organizations achieved the highest level of maturity in the governance component with an overall score of 3.58. Australian organizations came in second with a score of 3.15, followed by American companies with a score of 3.07. Latin American and European organizations earned scores of 3.03 and 2.94, respectively.

65.4.4 Partnership

The relationship that exists between the business and IT organizations is another criterion that ranks high among the enablers and inhibitors. Giving the IT function the opportunity to have an equal role in defining business strategies is obviously important. However, how each organization perceives the contribution of the other, the trust that develops among the participants, ensuring appropriate business sponsors and champions of IT endeavors, and the sharing of risks and rewards are all major contributors to mature alignment. This partnership should evolve to a point where IT both enables AND drives changes to both business processes and strategies. Naturally, this demands having a good business design where the CIO and CEO share a clearly defined vision.

For example, a large software development company assessed their partnership maturity at a level of 2. The IT function is mainly an enabler for the company. But IT does not have a seat at the business table, either with the enterprise or with the business function that is making decisions. In the majority of cases, there are no shared risks because only the business will fail. Indications are that the partnership criterion will rise from Level 2 to Level 3 as top management sees IT as an asset, and because of the very high enforcement of standards at the company.

Partnership for a large communications manufacturing company was assessed at Level 1. IT is perceived as a cost of being in the communications business. Little value is placed on the IT function. IT is perceived only as help desk support and network maintenance.

For a large utility company, partnership maturity was assessed at a level of 1+. IT charges back all expenses to the business. Most business executives see IT as a cost of doing business. There is heightened awareness that IT can be a critical enabler to success, but there is minimal acceptance of IT as a partner.

Partnership for a large computing services company was assessed at Level 2. Since the business executives pursued e-commerce, IT is seen as a business process enabler as demonstrated by the web development. Unfortunately, the business now assigns IT with the risks of the project. Most IT projects have an IT sponsor.

From a geographic perspective (as illustrated in Table 65.2), Asian organizations have a partnership maturity score of 3.64. The next closest region was Latin America, with a partnership score of 3.16. The American, Australian, and European partnership scores were 3.09, 2.96, and 2.78, respectively.

65.4.5 Scope and Architecture

This set of criteria tends to assess IT maturity. The extent to which IT is able to

- Go beyond the back office and into the front office of the organization
- Assume a role supporting a flexible infrastructure that is transparent to all business partners and customers
- Evaluate and apply emerging technologies effectively
- Enable or drive business processes and strategies as a true standard
- Provide solutions customizable to customer needs

Scope and architecture were assessed at a level of 2+ at a large software development company. This is another area where the company is moving from Level 2 to Level 3. ERP systems are installed and all projects are monitored at an enterprise level. Standards are integrated across the organization and enterprise architecture is integrated. It is only in the area of inter-enterprise that there is no formal integration.

A large financial services company assessed their scope and architecture at Level 1. Although standards are defined, there is no formal integration across the enterprise. At best, only functional integration exists.

Once again, Asian companies led in this dimension, scoring 3.6 for the scope and architecture component. Latin America came in second, with a score of 3.27, followed by the United States, which scored 3.12. European and Australian organizations scored 3.01 and 2.96, respectively.

65.4.6 Skills

Skills were defined in Figure 65.1. They include all of the human resource considerations for the organization. Going beyond the traditional considerations such as training, salary, performance feedback, and career opportunities are factors that include the organization's cultural and social environment. Is the organization ready for change in this dynamic environment? Do individuals feel personally responsible for business innovation? Can individuals and organizations learn quickly from their experience? Does the organization leverage innovative ideas and the spirit of entrepreneurship? These are some of the important conditions of mature organizations. The 362 Global 1000 benchmark firm results indicate that 55% of the benchmarked firms do not effectively support career crossover opportunities (IT into the business and the business into IT) and that 55% of the benchmarked firms do not effectively support education cross training.

For example, a large aerospace company assesses its skills maturity at Level 2. A definite command and control management style exists within IT and the businesses. Power resides within certain operating companies. Diverse business cultures abound. Getting to a non-political, trusting environment between the businesses and IT, where risks are shared and innovation and entrepreneurship thrive, is essential to achieve improvements in each of the other maturity tenets. Organizational behavior research has demonstrated that sharing information that is based on expertise is often the most successful approach to influencing others to cooperate and trust one another.[42]

Skills maturity at a large computing services company is assessed at a level of 1. Career crossover is not encouraged outside of top management. Innovation is dependent on the business unit, but in general is not encouraged. Management style is dependent on the business unit, but is usually command and control. Training is encouraged but left up to the individual employee.

Finally, from a geographic perspective, Asian companies earned a maturity score of 3.55. Latin American organizations came in second, earning a score of 3.00. American, European, and Australian organizations received SAM Skill scores of 2.84, 2.70, and 2.68, respectively.

Amazon.com—Alignment Maturity Enables Strategic Transformation

> "I buy books from Amazon.com because time is short and they have a big inventory and they're very reliable."
>
> **– Bill Gates**

> "I cannot live without books."
>
> **– Thomas Jefferson**

By now, everyone knows the brand Amazon.com and its transformation of the staid world of selling books via the Internet. Even the phrase "*being Amazoned*" has entered the business lexicon as synonymous with being blindsided by an unexpected competitor that uses e-business as an enabler of strategic transformation of the business (not to mention the industry). Could Amazon.com have impacted its industry as it did without a high level of SAM? Let us look at some facts about

(*continued*)

(**continued**)

Amazon—using the SAM criteria discussed earlier in this chapter—that might support the hypothesis that a high level of SAM contributed to Amazon's ability to transform the book sales industry:

- *Communications*—Jeff Bezos, the founder and CEO of Amazon, understood the power of IT to transform the business of selling books. Understanding of the enabling power of IT by the business (and vice versa) is part of the "warp and woof" of how Amazon operates. Without IT, there is no Amazon.com! Amazon's initial management team continuously reinforces its entrepreneurial culture with messages to its employees from Bezos and the executive team about Amazon's vision and philosophy ("being able to buy anything, anytime, anywhere at the greatest store on Earth …"). Employees understand that being with Amazon is about making history.
- *Competency/value measurements*—Amazon passionately focuses on the metrics of excellent customer service and the effectiveness of its advertising strategy. For example, Amazon produces a weekly report that shows the effectiveness of *each* online advertisement placed in terms of the customer traffic that was generated and the revenue for each customer visit to Amazon's site. Given the intense competition from other web retailers, Amazon continuously monitors its performance against its rivals and adjusts business processes to set the pace rather than react to changes in the environment.
- *Governance*—Amazon has divided its business into three segments: (1) "mature" businesses such as books, music, and DVDs that have to "pay their way," (2) "early-stage" businesses such as games, consumer electronics, and home improvement that need nurturing and feeding, and (3) Amazon's end user–based businesses. This governance model defines how decisions will be made regarding the investment Amazon will make in its IT portfolio and how that investment will be funded (i.e., self-funded or funded from outside investment). It is also clear that Jeff Bezos and a small, tight-knit group of executives make the key strategic business and IT decisions as IT strategy *drives* the business of Amazon.com.
- *Partnership*—It is clear from Amazon's business model—which is enabled through IT—that IT is valued as the engine of industry transformation. The high level of partnership between business and IT is driven by the vision of the CEO—Jeff Bezos—and continuously reinforced by Amazon's ability to coadapt its IT architecture to an evolving business model. Amazon has also heavily invested in other online retailers (members of its "Commerce Network") to extend its retailing capabilities to other products such as jewelry, consumer electronics, etc.
- *Scope and architecture*—The scope of Amazon's business and its IT architecture is driven by the external expectations of its customers. Amazon has implemented standard IT architectures around personalization features and order fulfillment that ensure consistent service to customers around the world.
- *Skills*—Amazon is known in the industry as a firm that aggressively recruits people who are bright, energetic, entrepreneurial, and customer-centric. Amazon's focus on hiring people who are skilled at personalization technologies and other "customer experience" technologies strengthened their brand and their reputation as being "absolutely fanatical about our customers." Amazon also developed deep expertise in fulfillment technologies ("picking, packing, and shipping") that are essential to delivering against high customer expectations of service.

In the discussion in the following section, we look at the different levels of SAM using the earlier criteria. What alignment maturity level would you assign to Amazon.com and why?

65.5 Results by Geography and Industry

As noted earlier, results from the assessment from the 362 Global 1000 companies by region reveal higher alignment scores by Asian organizations across all maturity components. As a group, they scored 3.58, as compared to 3.00 for the United States and 2.82 for Europe. A complete illustration of regional SAM scores by component is shown in Table 65.2 and Figure 65.5.

What was it that made Asian organizations score higher in every SAM component than their European, American, and Latin American counterparts? An examination of the factors that have led to the remarkable success of India's service sector offers several lessons. A strong culture that promotes communication between employees, the emphasis of CMM/CMMI-based continuous improvement efforts, and well-planned strategies that promote organizational flexibility are just some of the factors that are illustrated in the Wipro sidebar later in this chapter. These cases offer yet more evidence that achieving IT–business alignment is not a matter of finding a single "silver bullet."

An analysis of SAM data shows that the retail, hotel/entertainment, service, and insurance sectors performed well above the average SAM score of 3.09 in all dimensions. As noted in Table 65.3, these industries scored 3.62, 3.44, 3.31, and 3.26, respectively. (Note: There were relatively few retail and hotel/entertainment companies in the sample, however.) The most well-represented industry in the Global 1000 was the financial industry, which earned an overall SAM rating of 3.01. The manufacturing industry performed closest to the mean, with an overall average of 3.13.

India IT Service Case—Wipro

Wipro is a global IT service company, headquartered in Bangalore, India, that was established in 1945. It entered into IT services in the 1980s. Its revenues have grown at a CAGR of 21% over a six decade period. Today, it is a US$3.47 billion organization with over 66,000 employees with operations in 19 countries.

It is the world's first PCMM Level 5 software company and the first IT service company to use Six Sigma. Among the top 3 offshore business process outsourcing (BPO) service providers in the world, it has almost 600 clients. Wipro is a strategic partner to five of the top 10 most innovative companies in the world. It is also the world's first company outside the United States to receive the IEEE software process award. It is the largest independent R&D service provider in the world. It is the first Indian IT service provider to be awarded Gold-Level status in Microsoft's Windows Embedded Partner Program. It is the first to get the BS15000 certification for its global command center. It has 46 development centers across the globe. It is the pioneer in applying LEAN Manufacturing techniques to IT services.

Communications: Wipro's Foreign Language Initiative enables IT professionals to communicate effectively with international clients. Employees are encouraged to learn one or more foreign languages. The initiative also helps non-English-speaking IT professionals in the use of English for communicating effectively with business executives, since most of Wipro's clients are from English-speaking countries.

Value metrics: Wipro wishes to be the "Toyota of business services" and is on track to becoming the world's most efficient and effective IT service provider. It offers a full portfolio of IT services including systems integration, package implementation, software application development and maintenance, research and development services, and information systems outsourcing across a range of industries delivering benefits for customers with six sigma consistency for global organizations. Using their global delivery model, they have international benchmarks in execution excellence that has translated into measurable results for their global customers, which

(*continued*)

(**continued**)

includes 75% faster time to market, 35% cost savings, and 35% productivity enhancements. Wipro is one of the few Indian IT service firms having adopted web services as an independent practice in its business plan. The IT capabilities are being built around web services–oriented applications and services to its customers. In this context, the confidentiality, security, and integrity of organizations' data are paramount, especially as data are exchanged across the Internet. Web service standards have gone a long way to address those concerns.

Skills/HR: Wipro has opened centers in the United States (Atlanta, Georgia and Troy, Michigan) in a continuing trend of "reverse outsourcing." Cultural alignment and closer customer relationships are keys to competing successfully in providing high-end consulting services. The recruits for the Wipro's centers attend 3 months of training in India before starting jobs in the United States in software development and project management. Wipro is also scouting for training sites in the United States. Further, the opening of U.S. centers is also an alternative to getting visas for workers, since getting work visa these days is getting competitive. It has also earmarked as much as $250 million for expansion in Europe through acquisitions (mainly in Germany).

IT Service companies such as Wipro ensure that they are able to have a continuous flow of new engineers and IT people by reaching into India's "second-level" engineering colleges to hire people before their last semester of study and then provide job-related course materials and training for that last semester. International campus hiring has also been initiated across the United States, Europe, and Asia to attract top talent. By doing so, Wipro is able to get commitments from students as they are just becoming ready to take on their first jobs after graduation, and with less in-house training. Only 1 out of 10 candidates gets interviewed, following a 1:50 ratio of resumes scanned, all enabled by IT.

HR counsels every employee on their strengths and weaknesses based on their profile by providing a map of courses to take at Wipro. There is a 40 day "Project Readiness Program" for new IT employees. Also, online study is encouraged. Wipro supplements a continuing education program for those who choose to enroll at leading educational institutes to obtain special skills in areas such as project management. At the leadership institute for senior managers, managers teach other managers business skills. Five percent of billable time is spent on training. The Chairman of Wipro himself spends half a day of his personal time teaching in every leadership program. Wipro offers 100,000 person days of training a year.

Partnership: At Wipro, everyone is encouraged to come up with big or small ideas, which would improve serving the customer/client. The idea is not to break new ground in basic knowledge, but in improving customer service. Wipro ties the rewards to performance.

An entry-level IT person moves onto a higher salary/benefits curve as they progress in completing assigned course/seminars that are geared to transform them from a computer science/engineering/business graduate into a software engineer. The "Wipro Equity Rewards Trust" plan gave Wiproites the benefits of participating in the wealth creation back in the 1980s. The stock option along with Quarterly Performance Linked Compensation (QPLC) provides innovative idea for linking Wipro's performance with employee compensation.

Governance: Wipro's technical competency lies in its ability to apply formal processes to ensure on time delivery, significant investments in accelerators, and partnerships and alliances. For Wipro, the nature of client trust is very important. IT tries to look at the problems the clients (internal and external) are experiencing and invites them to discussions to identify opportunities for the

(*continued*)

(**continued**)

future growth of the firm. They push the business verticals to think aggressively about future opportunities to prepare for the challenges the company might face. At Wipro, IT governance practices help clients in the realization of IT and business objectives through process performance optimization and compliance in areas of IT governance. They digitize their leading IT and process initiatives using workflow-based approaches that lead to easy adaptation and adoption of frameworks such as CMMI, Six Sigma, and ITIL.

Technology scope and architecture: Wipro is very cognizant of the fact that they need to remodel their processes and technical foundation to ensure that the IT systems are scalable. They have created autonomous structures combining IT, process, and applications that will allow them to continue the same growth in the future, while making sure that the data from the legacy systems are not lost by incorporating middleware technologies. Mobile applications are also a top priority at Wipro. With more than 50 offices in India and 30 offices abroad, scalability and flexibility are fundamental. Different geographic locations have different IT requirement and Wipro's IT infrastructure conforms to each of the locations in a flexible manner to ensure effectiveness/efficiency.The Internet is the key enabler of their infrastructure. In addition to physical security measures, frequent information audits are carried out to ensure a secure environment. As Wipro keeps hiring more employees, IT enables scalability in the HR process.

In summary, Wipro is one of the largest support service providers worldwide. It has the distinction of being the first PCMM Level 5 and SEI CMM Level 5 certified IT Services organization globally. Wipro provides comprehensive research and development services, IT solutions and services, including systems integration, information systems outsourcing, package implementation, software application development, and maintenance services to corporations globally. IT and business units are aligned well and are able to maximize IT business value, service delivery and are able to reduce the IT cost. They are successful at tracking all requests coming into IT and demonstrate value added to business. There is increased visibility and transparency through dashboards, improved productivity and data accuracy. ROI is high because of the implementation of a rational, sound portfolio management process for selecting more suitable IT projects aligned to business goals.

65.6 Strategic Alignment as a Process

Attaining and sustaining business–IT alignment must first focus on understanding the current level of SAM. This should be followed by steps that concentrate organizational energy on maximizing alignment enablers and minimizing inhibitors. This process embraces the steps[10] illustrated by Figure 65.7 and elaborated in the following text:

1. *Set the goals and establish a team*. Ensure that there is an executive business sponsor and champion for the assessment. Next, assign a team of both business and IT leaders. Obtaining appropriate representatives from the major business functional organizations (e.g., marketing, finance, R&D, and engineering) is critical to the success of the assessment. The purpose of the team is to evaluate the maturity of the business–IT alignment. Once the maturity is understood, the team is expected to define opportunities for enhancing the harmonious relationship of business and IT. Assessments range from 3 to 12 half-day sessions. The time demanded depends on the number of participants, the degree of consensus required, and the detail of the recommendations to carry out.

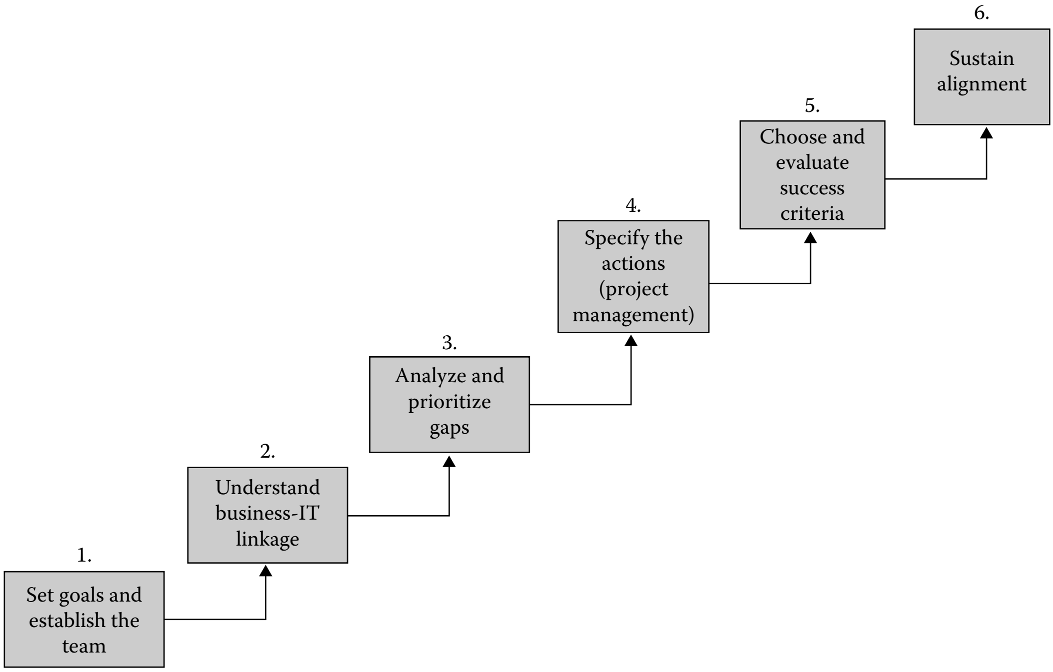

FIGURE 65.7 Strategic alignment as a process.

2. *Understand the business–IT linkage*. The SAM Assessment is an important tool in understanding the business–IT linkage. The team evaluates each of the six criteria. This can be done via executive interviews, group discussion, a questionnaire, or a combination. A trained facilitator can be valuable in guiding the important discussions.
3. *Analyze and prioritize gaps*. Recognize that the different opinions raised by the participants are indicative of the alignment opportunities that exist. Once understood, the group needs to converge on a maturity level. The team must remember that the purpose of this step is to understand the activities necessary to improve the business–IT linkage. The gaps between where the organization is today and where the team believes it needs to be are the gaps that need to be prioritized. Apply the next higher level of maturity as a roadmap to identify what can be done next.
4. *Specify the actions (project management)*. Knowing where the organization is with regard to alignment maturity will drive what specific actions are appropriate to enhance IT–business alignment. Assign specific remedial tasks with clearly defined deliverables, ownership, timeframes, resources, risks, and measurements to each of the prioritized gaps.
5. *Choose and evaluate success criteria*. This step necessitates revisiting the goals and regularly discussing the measurement criteria identified to evaluate the implementation of the project plans. The review of the measurements should serve as a learning vehicle to understand how and why the objectives are or are not being met.
6. *Sustain alignment*. Some problems will just not go away. Why are so many of the inhibitors IT related? Obtaining IT–business alignment is a difficult task. This last step in the process is often the most difficult. To sustain the benefit from IT, an "alignment behavior" must be developed and cultivated. The criteria described to assess alignment maturity provide characteristics of organizations that link IT and business strategies. By adopting these behaviors, companies can increase their potential for a more mature alignment assessment and improve their ability to gain business value from investments in IT. Hence, the continued focus on understanding the alignment

maturity for an organization and taking the necessary action to improve the IT–business harmony are keys. Implicit in this is to periodically repeat the process to see how the organization evolves over time.

Fundamental to the effective use of the SAM assessment is not only to measure the maturity level of IT–business alignment but also to identify the problem/opportunity areas; and more important use the model as a roadmap to define specific initiatives for improvement. Repeating the assessment periodically can be insightful.

For example, when the SAM model was first used to assess the level of alignment maturity for a large financial company (fictitiously referred to as Stonehenge), they were assessed at Level 2 (committed processes). At the time, Stonehenge had recently adopted the federated IT organization model, so no one considered that the IT organization structure would be the area to consider in identifying why this financial giant was only at Level 2. After all, the federal (or hybrid) IT organization design has been found to produce higher alignment maturity scores over centralized and decentralized IT organization alternatives, because it captures the benefits of both centralized and decentralized IT organizations. The federated IT organization deployed at Stonehenge essentially centralized IT architecture and common systems, while decentralizing the strategic business unit applications and resources. The centralized IT structure supports the development of strong and efficient IT infrastructures while the decentralized IT group fosters business–IT relationships. Following the aforementioned logic, Stonehenge had decentralized its formally centralized application development staff, expecting that the relationships with the business management would improve. However, the analysis of the Stonehenge SAM assessment data showed the following:

- The indicators that measure the understanding of business by IT and the understanding of IT by business, which are covered in the "communications" area of the SAM model, were very low. Knowledge sharing in the organization was at a minimum to none. IT and business met occasionally (only during major walkthroughs) in a formal setting.
- IT–business relationship and trust measures that are covered under the "partnership" area were also at the minimum. Business viewed IT as a cost of doing business. There was an ongoing conflict between business and IT; they blamed each other for every late or unsuccessful delivery.
- Competency metrics—Measuring value of IT area showed that IT operated as a cost center.
- Social interaction indicator, which is covered under the HR area, was pointing to minimal IT–business interaction.

These and several other criteria used in the assessment suggested that there was conflict in the IT–business relationship in Stonehenge and that trust levels were at a minimum—typical in a centralized IT organization with poor linkages between business and IT. The fact that the company had already adopted the federated model motivated managers to further analyze the data to find out why the relationship with the business management did not improve.

Several other indicators, such as the differences between the IT and the business managers' opinions and the differences between the top and the middle managers' opinions in the SAM model, pointed to the problem in the implementation of the federated model. Looking at the organization charts and the grouping of the departments, they seemed in line with the federated model, meaning that the application development groups were created within the business units and dual reporting relationship for the divisional IT heads was created. Yet, the location of the development teams and the way they were functioning were not different from what they would be like in a typical centralized IT organization. At the end of the study, it was apparent that the management could not diverge from the routine they followed for many years. Indicators such as the tendency of the employees' resistance to change (measured in the HR area) were also in support of this hypothesis.

As illustrated in this example, SAM not only helped identify Stonehenge's maturity score, but it also allowed managers to identify specific problems and opportunities to improve the IT–business alignment.

Once again, organizations should not be in pursuit of a silver bullet. All six components of alignment maturity should be considered to determine the areas that require improvements and the opportunities that exist to help improve the IT–business alignment maturity level of the organization.

The periodical SAM measurement and results at Stonehenge are reviewed by both business and IT managers to ensure appropriate alignment. SAM provides guidance for business changes as well for a better alignment. SAM assessment should be considered as a continuous process of improvement in the organizations facing turbulent changes in business environment to enable organization-led increased SAM in the organization.

65.7 Strategic Alignment Maturity and Business Performance

The concept of performance underlies a lot of the research in strategic management and information science. A broader conceptualization of business performance would include emphasis on indicators of operational performance in addition to indicators of financial performance. Under this conceptualization, it would be logical to treat measurements such as market share, new product introduction, product quality, marketing effectiveness, manufacturing value added, and other measurements of technological efficiency within the domain of business performance.

Research done by Luftman et al. validated the contribution of SAM to company performance based on the data gathered from 362 global organizations across four continents.[24] The research identified that the six SAM components (communications, IT governance, value, partnership, technology scope, and skills) have approximately equal contribution to form the overall SAM score and they are strongly correlated to each other, as illustrated in Figure 65.8 through 65.10. Regarding the relationship of SAM and company performance, the regression weight (0.34) for SAM in the prediction of performance is significant; hence, this proves the contribution of SAM as a major contributor to a company's performance (see Figure 65.8). This relationship was found to be valid across all industry types, cultures, and geographic locations.

In addition, research has shown that the organization's structure—whether it follows a centralized, decentralized, or federated model—also has an impact on SAM maturity (see Figure 65.10). Notably, companies with federated IT structures are able to combine the benefits of centralized structures

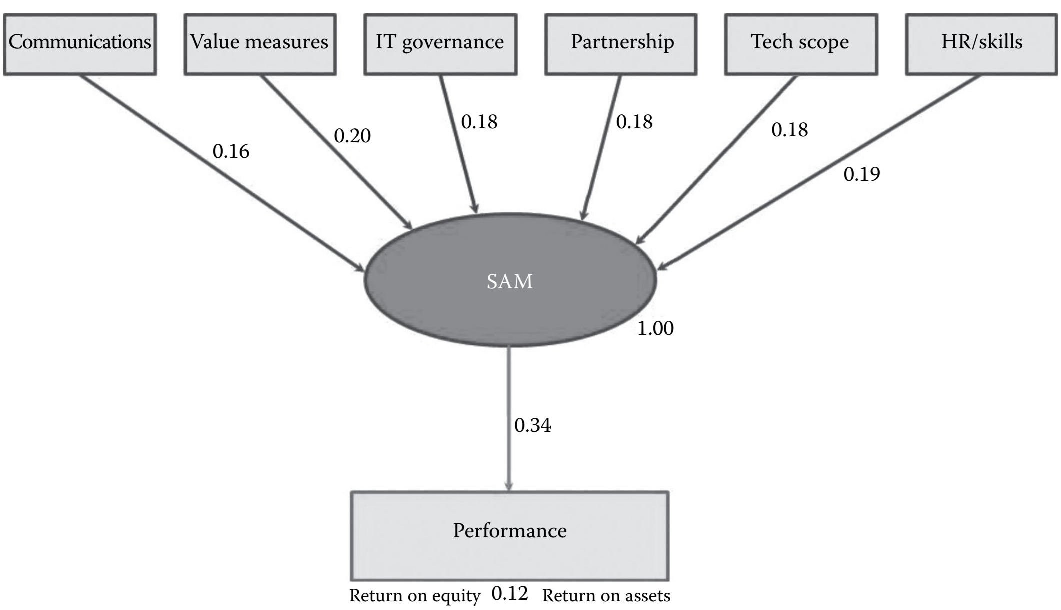

FIGURE 65.8 Structural equation model validation (1).

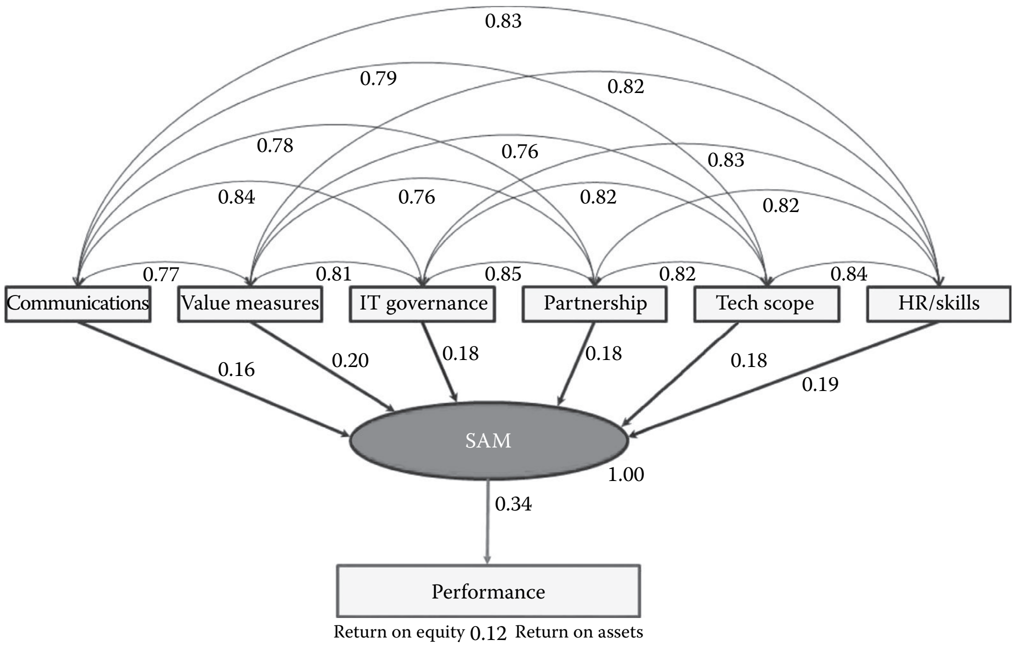

FIGURE 65.9 Structural equation model validation (2).

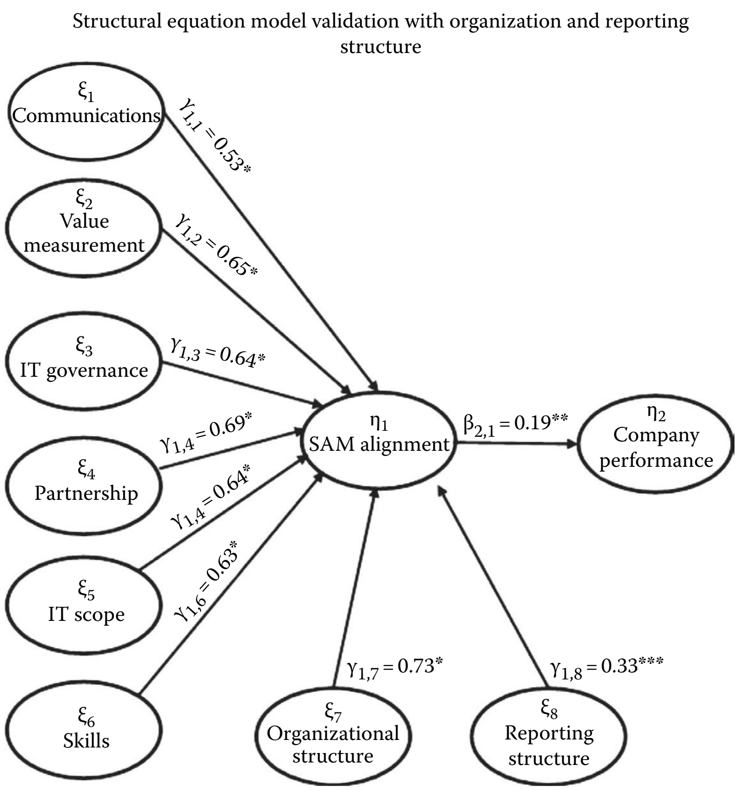

FIGURE 65.10 Structural equation model validation (3). (From Earl, M.J., *Corporate Information Systems Management*, Richard D. Irwin, Inc., Homewood, IL, 1993.)

(such as standardization and economies of scale) and decentralized structures (local flexibility and control). These companies tend to have higher alignment maturity ratings.[24]

This relationship also supports the contention that achieving alignment is not a matter of addressing a single "magic bullet" issue. If IT–business alignment leads to better performing organizations, then the implication is inescapable. An organization that fixates on one component at the expense of others is all but certain to be an underperforming organization.

This research builds upon the work done in 1993 by Henderson and Venkatraman,[23] whose strategic alignment framework was based on four components: business strategy, IT strategy, organizational infrastructure, and IT infrastructure. This was the first time that a strategic alignment framework was used by both researchers and practitioners in the field.

65.8 Conclusions

Achieving and sustaining IT–business alignment continues to be a major issue. Experience shows that no single activity will enable a firm to attain and sustain alignment. There are no silver bullets. The technology and business environments are too dynamic. The research to derive the business–IT alignment maturity assessment has just begun and the tools and processes are still being refined.

Much work still needs to be done to refine hypotheses around SAM and to measure its impact on organizations and their ability to execute strategy.

Research conducted over the course of a decade clearly shows that companies are getting better at aligning their business and IT; albeit alignment is still a pervasive and persistent problem. Overall maturity scores have increased from 2.99 in 2000–2003 to 3.17 in 2009–2010. There is evidence that higher levels of alignment have positive effects on company performance *regardless of industry type or organization structure*. However, results from the assessment of 362 Global 1000 companies demonstrate that some industries clearly do a better job of aligning their IT and business operations than others. Additional studies have linked high alignment maturity levels with better company performance measures, including sales, productivity, ROI, ROA, ROE, and NPM. The research also indicates that there are differences by region. This suggests that the strategic alignment of a company may depend both on industry norms and on local factors.

Achieving significantly higher levels of IT–business alignment across a wider range of organizations is a long-term journey. The journey in each organization begins with a complete assessment of how business views IT, and how IT views business. The journey continues with how business and IT executives work together to close the gaps and improve the performance of the organization. In the quest for continuous improvement within a dynamic global environment, the journey may never end.

Process of Information Systems Strategizing: Review and Synthesis

Anna Karpovsky
Bentley University

Mikko Hallanoro
University of Turku

Robert D. Galliers
Bentley University

66.1 Introduction

This chapter reflects on the developments in research on information systems (IS*) strategy and the process of IS strategizing. In reviewing the literature base, we have developed an integrative framework that captures key concepts and processes that are associated with IS strategizing. By summarizing the research themes and constructs found in the literature, we trust that the framework will serve as a sense-making device for current and future IS strategy researchers; something that sets the scene in terms of the extant research that might form a useful basis for identifying potential future areas of research. By emphasizing the processes relevant for IS strategizing in practice, we also hope the framework will be a practical aid for those who plan and strategize around IS.

* As the terms *information technology* (IT) and *information systems* (IS) have been used interchangeably in the literature, the authors will use the terms used by the original authors when referring to the earlier work. Note, however, that we differentiate between the two terms ourselves when analyzing the literature and drawing our conclusions.

First, though, we will present some common definitions associated with the noun—strategy, and the verb—strategize, as a basis for our treatment of the subject matter. The *Webster* and *Oxford* dictionaries define strategy, *inter alia*, as

- A plan of action designed to achieve a long-term or overall aim*
- The art of devising or employing plans or stratagems toward a goal
- An adaptation or complex of adaptations (as of behavior, metabolism, or structure) that serves or appears to serve an important function in achieving evolutionary success†

Further, *Webster* defines strategize as

- "to devise a strategy or course of action"

From these definitions, we may conclude that these terms relate to a means of achieving a goal or aim but that there is some debate about whether such plans are deliberate and sequential in nature or are more evolutionary and adaptive. This is a debate to which we will return. For now, though, let us assume that the process of strategizing combines both of these elements.

As regards IS, we take the following, inclusive meaning of the term: "the entire infrastructure, organization, personnel, and components that collect, process, store, transmit, display, disseminate, and act on information."‡ Thus, when we talk of IS strategizing, we see this is a process that will lead to actions being taken that will relate to the sociotechnical concept of infrastructure that is introduced earlier.

We begin this chapter with a historical treatment of the topic in order to provide some background for what follows.

66.2 Historical Background: From Data Processing to Strategic Information Systems and Beyond

66.2.1 Data Processing

At the time of the development of the first commercial applications of information technologies (IT) in the early 1950s,§ most people regarded computers as massive machines that scientists used to find solutions to computationally intensive equations that would take a human being a number of years to solve. In the late 1960s, companies with highly data-driven tasks operated these large, centralized computer systems that typically ran batch jobs to process the daily transactions for their businesses. This early era is often referred to as the *data processing era*. At that time, the business objective was to automate information-based processes in order to improve operational competence by reducing data processing costs and, consequently, achieving business efficiency (Galliers, 1991). Among the problems of that period were huge maintenance costs, duplication of data, incompatible application systems, and—often—overall user dissatisfaction (Somogyi and Galliers, 1987). In addition, in some cases there was little or no direct link between the business strategy (i.e., objectives and goals) and the IS plan. The IS plan, if one existed, and the IS operations of the organization were predominately concerned with the efficient operation of computer technology for operational purposes and tended to be isolated (Galliers, 2004) or independent (Teo and King, 1997) from the business of the organization.

§ See Caminer et al. (1998) for an account of the world's first business computer, LEO, which was developed in the United Kingdom and introduced in 1951.

66.2.2 MIS

In the 1970s, with the emergence of "minicomputers" that featured increasing power and sophistication, computer systems began to offer solutions to a higher level of decision capability. As more data became stored, managers realized that using the output of IS—information—could increase the effectiveness of their decision-making (Ward and Peppard, 2002). Such developments denoted the beginning of what can be termed the *management information systems* (MIS) *era*. The objective of MIS was to create ways of organizing and delivering information in order to improve management effectiveness. There was growing demand among management to have business-driven IS capable of dealing with business problems and the issues managers faced (Galliers, 1991). MIS reports (printouts) were provided at regular intervals (e.g., monthly); they were intended to provide managers with the information they needed, primarily for control purposes.

The first signals for the need for strategic IS planning appeared in this era since it was considered that strategic planning for the information needs of the organization was both feasible and necessary if MIS were to support its basic purposes and goals (King, 1978). The data processing applications of the earlier era produced "at best fragmented data, at worst a chaotic mess of data with little or no integrity" (Ward and Peppard, 2002, p. 18). As a result, thinking began to focus more on organization-wide information (i.e., what information is used, how it is used in the organization, and what more might be needed).

One of the most influential publications during the MIS era is arguably Nolan's (1979) article that presents the so-called stages of growth model. This had remarkable impact on the development of IS strategizing, being both highly cited in the academic literature and extensively applied in practice, leading to the founding of Nolan, Norton & Co., which was subsequently acquired by KPMG. First published by Nolan (1973) and Gibson and Nolan (1974), the model was not without its critics, however. For example, it was criticized for its lack of empirical substantiation, the overly simplistic assumptions on which it was based, and the limited focus of the original concept (Benbasat et al., 1984; King and Kraemer, 1984). Nonetheless, it had a major impact, and since the original publication of the model was published, it has gone through several refinements and revisions by numerous authors (e.g., Earl, 1988, 1989; Nolan, 1979, 1984), and also later by Galliers and Sutherland (1991). The latter developed a revised model with a broader view concerning strategic, organizational, human resource, and management issues. Thus, notwithstanding the criticisms, the concept—in its various forms—has been applied extensively.

More generally, in an early paper, McFarlan (1971) pointed to the fact that little IS planning was taking place: of the 15 companies he studied, only one had been planning for IS for 4 years while the rest had just considered planning as a potentially necessary activity. During these early days, a handful of articles and books on the topic began to appear, in the United States for the most part (Lincoln, 1975 being an exception), each in their way concerned with the strategic dimensions and potential impacts of computer usage in organizations (e.g., Blumenthal, 1969; King and Cleland, 1975; Kriebel, 1968; McFarlan, 1971; Nolan, 1973; Siegal, 1975; Schwartz, 1970; Young, 1967). The earliest of the journal articles that specifically addressed the process of planning and strategizing for IS are listed in Table 66.1.

Young (1967) listed a number of convincing reasons and benefits of planning for IS. These included the promotion of a better organizational decision-making process through the management of information. Kriebel (1968) argued that an intuitive, ad hoc approach to planning for computers does not work; rather, organizations should develop strategies that define the role of computers in "attaining the strategic objectives of the corporation" and establishing planning objectives on the basis of organizational goals. Assessment of an organization's status in terms of systems development, resource commitment, and management organization for computer systems were all considered to be important decisions in a "company computer strategy" (ibid., 12).

Schwartz (1970) also promoted planning for MIS, stating that the starting point should be a determination of management and user needs. He proposed a specific "systematic and analytic" approach to planning that takes an evolutionary perspective (i.e., a planning–executing–learning–planning

cycle framework). Identification of current and potential systems and evaluation of needed resources are present in the Schwartz framework, with implementation and feedback mechanisms being emphasized in this early work. Similarly, King and Cleland (1975) promoted a "systems approach" to planning, where the entire focus was on a feedback (learning) process, where plans depend on the consequences of action just as intrinsically as actions reflect the results of planning.

Other early works on approaches to IS planning included those by Zani (1970), Nolan (1973), and Lincoln (1975), as notable examples. Zani (1970) suggested that the bottom-up approaches of the earlier era produce benefits mostly by chance. Conversely, the top-down approach he advocated helps in establishing goals and priorities for MIS development and therefore focuses IT where it is most needed. While developing the first version of the stages of growth model, Nolan (1973) found a "database/key-task strategy" to be most effective since management would have to consider carefully what the key tasks of the business are, thereby forcing on cross-functional data integration. Lincoln's (1975) approach was built, first and foremost, on an understanding of the business function in terms of objectives and tasks; only after this has been achieved could information requirements to meet defined objectives be examined.

This early research viewed IS plans and strategies as mainly reactive to business strategies, and managers strove to align their IS strategies with their business needs. For example, King and Cleland (1975) framed their discussion around transformation of organizational mission, objectives, and strategies into "IS strategy sets." These ideas were later adopted by IBM as a basis for their Business Systems Planning (BSP) methodology. This methodology was used in many organizations, not just in the United States. It was—frankly—as much a marketing device for IBM mainframes as well as a consulting tool, given the added value of such strategic services IBM was able to offer, compared to other vendors.

66.2.3 SIS

By the late 1980s, there were growing numbers of cases in which IT was shown to have had a strategic impact on organizations. Though the studies undertaken in the United States tended to assume that in almost every instance IS planning is undertaken, and the emphasis was on questions "how" and "why," this was less the case with their British or Australian counterparts, for example, where the emphasis remained on question "whether" any planning was undertaken (Galliers, 1987, p. 51), notwithstanding the early work of the likes of Michael Earl (e.g., Earl, 1988, 1989). Nevertheless, corporate executives became increasingly interested in what were termed strategic information systems (SIS). The objective of the *SIS era* was to change the nature or conduct of business in order to improve the competitiveness of the company—a proactive, rather than reactive approach in other words. The American Airline's SABRE reservation system was one such oft-cited SIS (e.g., McFarlan, 1984; Porter and Millar, 1985). The use of IS began to influence organizations' competitive positions and became a strategic weapon for competitive advantage (Ward and Peppard, 2002).

Research identified a number of organizational and individual factors that promoted the development of SIS. A competitive market was found to be conducive to the development of SIS (King and Sabherwal, 1992). An internal need was found to be the reason for SIS development in 14 well-known SIS (Neo, 1988). Automation to enhance internal efficiency had become crucial for products and processes with high information content (Lindsey et al., 1990). Similarly, businesses with high transaction volumes built systems to improve internal operations (Johnston and Carrico, 1988).

A significant portion of the early SIS literature was devoted to the identification and description of opportunities for SIS. SIS planning (SISP) approaches were developed to identify these strategic opportunities for organizations by applying IT to optimize business performance (Pant and Ravichandran, 2001) and were, as a result, labeled as "impact" mode approaches (Bergeron et al., 1991). For example, Lederer and Sethi (1996, p. 1) define SISP as "the process of identifying a portfolio of computer-based applications that will assist an organization in executing its business plans and realizing its business goals."

During the SIS and SISP era, the purpose of IS strategic planning was both to influence and enable a business strategy and to support it (King and Teo, 1997). IS strategies were viewed as proactive, and attention shifted to how the technology can be employed to increase competitive advantage through analyses of the competitive environment and internal processes (Galliers, 2004).

66.2.4 Summary: Toward Sustainability and Capability

Summarizing the early developments in IT, Galliers (1987, 2004) suggests that the focus of IS strategizing during those earlier periods went through four phases during which attention shifted away from and then back to IT, and from matters of efficiency to matters of effectiveness and competitiveness. The four phases mirror, to some degree, the eras identified earlier: isolation (the data processing era), re-action and prospection (the MIS era), and pro-action (the SIS era). Figure 66.1 describes the development in terms of the degree to which the IS strategy might be viewed as a business-driven, "top-down" process—as opposed to more technology-driven, "bottom-up" concerns—and the extent to which such strategies have been based on short-term problem solving as opposed to more long-term strategic goal setting. Galliers (2004) suggests that, in some respects, current IS strategizing includes characteristics of each of these "phases." Similarly, Peppard and Ward (2004) note that, with the evolution of IT, each "era" displays different characteristics regarding the application of IT and has different objectives. In this sense, every new era or phase in IT evolution and IS strategic planning encompasses the earlier views as well.

More recently, there has been an increased interest in the question of the sustainability of the competitive advantage to be derived from IS (Ward and Peppard, 2002). Even though an organization can gain a competitive advantage over others in the short run, such as from the "first mover advantage" gained through an innovative application (Clemons and Row, 1991; Mata et al., 1995), most of these technologies can be easily copied and, therefore, do not produce a sustainable competitive advantage. Unlike competitive advantage, sustainability is an ongoing state that creates continuous advantage (Barney, 1991).

Valuable, rare, inimitable, and non-substitutable (the so-called VRIN) resources are considered to be a source of sustainable competitive advantage based on the resource-based view (RBV) of the firm (Barney, 1991; Rumelt, 1984; Wernerfelt, 1984). According to Wang and Ahmed (2007, p. 3), "The essence of the RBV lies in the emphasis on resources and capabilities as the genesis of competitive advantage: resources are heterogeneously distributed across competing firms and are imperfectly mobile which, in turn, makes this heterogeneity persist over time." Traditionally IS has been associated with technological systems, which—indeed—are often rather easy to imitate or substitute (cf. recent arguments by

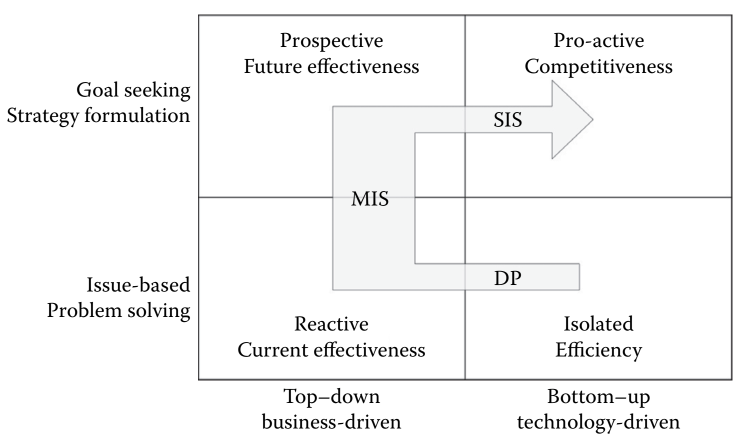

FIGURE 66.1 Developments in IS strategizing. (From Galliers, R.D., in Galliers, R.D. and Leidner, D.E. (Eds.), *Strategic Information Management*, 4th edn., 2009, Oxford University Press, Oxford, U.K.)

the likes of Carr, 2003, for example). However, the RBV and its derivatives such as the capabilities view facilitate the consideration of IS holistically, including, for example, the organization's external environment, internal processes, organizational culture, and employee resources—all of which are considerably harder to imitate or substitute. With respect to strategic planning, the resource-based perspective also places importance on managerial strategies for developing new capabilities (Wernerfelt, 1984).

Ross et al. (1996) and Bharadwaj (2000) introduce the concept of IS capability as something that organizations need to develop to enhance competitiveness. Specifically, Bharadwaj et al. (2002, p. 4) combine earlier works and definitions to define IT capability as a "firm's ability to acquire, deploy, and leverage its IT resources to shape and support its business strategies and value chain activities." Further, Pavlou and El Sawy (2006, p. 198) suggest that "IS researchers should look beyond the direct effects of firm-level IT infrastructures and focus their attention on how business units can leverage IT functionalities to better reconfigure and execute business processes." They list various IT-related resources that, when combined, form IT capability, including many nontechnical resources such as access to capital, proprietary ownership, managerial IT skills, IT–business partnering relationships, IT human resources, complementary IT human and business resources, and business process integration. A somewhat similar perspective is provided by Galliers and Sutherland (1991), based on their amendment of the stages of growth model (Gibson and Nolan, 1974; Nolan, 1973, 1979), which incorporated the so-called 7S framework, used by McKinsey (i.e., shared values, strategy, structure, skills, staff, style, and systems).

Other scholars have provided additional insights on IS capabilities. For example, Kettinger et al. (1994) conclude that gaining IT/IS-based sustained competitive advantage is a matter of building organizational infrastructure. Powell and Dent-Micallef (1997) suggest that some organizations have been successful in using IT to leverage intangibles and human resources such as organizational flexibility, integrating business and strategy planning, and vendor relationships. Mata et al. (1995) argue that IS management skills are the only source of sustained advantage.

The growing complexity of both business processes and IS together with commodity nature of IT has shifted the main focus of attention from technical aspects to the organizational factors enabling effective exploitation of IT. As mentioned earlier, the IS capabilities view emphasizes the development and delivery of all IS-related organizational capabilities rather than the straightforward development of IS systems or simple recognition of promising opportunities. DP-, MIS-, and SIS-era planning methodologies concentrated on introducing more effective IS solutions, recognizing new opportunities, and improving production processes. The IS capability view is, however, concerned mainly with introducing and developing the capabilities to fulfill the DP-, MIS-, and SIS-era objectives. It can, thus, be considered another step forward in the transformation from asking questions of "what" to the questions of "how" and "why." While an SIS-era IS strategy might envision the strategic IS opportunities and systems that will be introduced to gain competitive advantage, "… in the IS capability era, the strategic management of IS is about developing IS competencies" (Peppard and Ward, 2004, p. 188).

Among several other researchers, Benamati and Lederer (2001, p. 86) point out that, facing the challenges of the information era, "organizations do not cope very effectively with rapid IT change." The RBV has been criticized and considered inadequate to explain sustained competitive advantage especially in changing environments. Consequently, faced with turbulent business environments and to further address the need to quickly deliver IS services, the IS dynamic capabilities view was introduced. The concept has been mentioned earlier in both business and IS literature and the ideas have been discussed well before the label "dynamic capabilities" was coined. Nevertheless, it received little serious attention before being popularized by Teece et al. (1992, 1997) and Eisenhardt and Martin (2000).

The dynamic capabilities construct is based on the idea that sustainable competitive advantage requires the ability to manage an organization in such a way that it can build successive temporary advantages by effectively responding to successive environmental shocks (Eisenhardt and Martin, 2000; Peppard and Ward, 2004). Teece et al. (1997, p. 516) define the concept as "The firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments." Following Barreto's (2010, p. 260) conclusions, dynamic capabilities have been identified as abilities,

capacities, and capabilities but also more specifically as processes, routines, learned and stable activities, or as a behavioral orientation that helps organizations to change. The challenge to keep up with the change requirements for IS has led to a growing need for attention for flexibility, agility, and change readiness in all aspects of utilizing IT. Rapid business change places a further challenge to plan for organizational change readiness, agility, and flexibility. Given today's high level of dependence on technology, IS strategizing and planning for IS dynamic capabilities become ever more important.*

Today, few people would disagree that the strategic management of data, information, resources, and knowledge—and the associated IT—represents a major strategic challenge and opportunity for organizations (Galliers, 2004). Of course, the value to an organization is not so much *what* specific technologies it has or develops, but *how* these technologies are employed. As such, strategizing about IS (Galliers, 2007), and the resulting IS strategy, when effectively engaged, may distinguish the performance improvements attributable to IS from one organization relative to others. Without an IS strategy, the contribution of IS to organizational performance is likely to be a result of serendipity (ibid.). Both practice and research have emphasized the need to carefully construct an IS strategy to complement and/or enable organizational objectives—as identified in the business strategy (Reich and Benbasat, 1996). IT strategic planning has remained among IT management's top 10 concerns throughout the last three decades (Luftman and Ben-Zvi, 2010). Understanding the strategic value of IS (i.e., seen holistically) has been a key goal of many IS practitioners and researchers (Galliers, 1993a,b; Luftman et al., 2006). Thus, considerable attention has been paid in the literature to, for example, addressing issues associated with IS strategic planning, alignment of IS and business strategies, and strategy formulation involvement (Chen et al., 2010).

Building on this introduction, the purpose of this chapter is to summarize developments of the field of IS strategy and the process of IS strategizing. First, we address the question of the conceptualization of IS strategy. A variety of terms, such as IT strategy (Gottschalk, 1999), IS/IT strategy (Chan et al., 1997), information management (IM) strategy (Karimi and Konsynski, 1991), and information strategy (Smits et al., 1997), have been used that are related to and sometimes used interchangeably with the term of IS strategy. We aim to clarify the distinctions and the connections among these terms. Second, we describe the evolution of the field and various streams of thought that have been considered in the course of the field's development. Last, in an attempt to synthesize extant research themes, we propose an integrative framework that links the various topics that encompass what we refer to as the research on the *IS strategizing process*.

66.3 Underlying Principles

66.3.1 IS Strategy Components

The foundational work on conceptualization of IS strategy was led—most notably—by Earl (1989) and developed further by Galliers (1991, 1999). Earl's (1989) insightful contribution was to differentiate the "what" from the "how" and the "wherefore" of IS strategy. In so doing, Earl makes clear that IS strategy is very much a business management issue, while IT strategy lies, for the most part, within the domain of the IT function. IS strategy comprises an application development portfolio, a "shopping list" of application and projects—the "demand" side of the IS strategy in other words. IT strategy is regarded as the "supply" side of the IS strategy. IT strategy is concerned with alternative technological solutions (alternative "hows") to support the "what" of business needs, thereby enabling IT to be better aligned with the business strategy. The "wherefore" indicates the kind of developmental path that needs to be taken to achieve this alignment. Other notable authors in this sphere include Lederer, who could

* For further information about the construct, recent literature reviews in the organization management literature by Barreto (2010), Ambrosini and Bowman (2009), and Wang and Ahmed (2007) list the main ideas, theories, and criticisms. Further, Schwarz et al. (2010) and Chen et al. (2008) have studied more closely the importance of dynamic capabilities for IS impact and alignment in organizations.

arguably—measured by the number of published and highly cited IS strategy articles in peer-reviewed journals—deserve the title of most influential academic contributor to IS strategy research. His most cited works related to IS strategy cover such topics as SISP methodologies, critical issues, implementation, information resource planning, key prescriptions, and SISP conceptualization (Lederer and Salmela, 1996; Lederer and Sethi, 1988, 1996).

Galliers' (1991) amendment to Earl's earlier conceptualization was to suggest that an *information* strategy might provide a useful distinction from IS or IT strategy in that it focuses on identifying the information that could question taken-for-granted assumptions on which the business strategy is based, as well as providing the information required by the business strategy. Thus, an information strategy is the glue between the business strategy and the IS strategy. It tends to answer questions such as "what is the information required to support primary tasks, or key goals, of the organization strategy?" and "where can this be obtained?" The information strategy also questions the business strategy by attempting to answer the "why" questions—"why might this particular strategy be chosen as against any other?" (Galliers, 2009).

A further distinction provided by Galliers (2009) is the *information services* strategy (also sometimes referred to as the IM strategy). An information services strategy focuses on policy issues regarding the organization of information services (and capabilities), including sourcing decisions—that is, "the organizational arrangements for the provision of IS-related services" (ibid., p. 14). This component of IS strategy mainly answers to the "who?" questions: who is needed to facilitate and enable the strategy to be developed and implemented. Such questions include considerations of the structure, roles, and processes of the IT function. Human resource issues, such as IT personnel requirements and choices between the internal service provision, also need to be considered. In this sense, it is a precursor to Peppard and Ward's (2004) call for a focus on IS capability discussed in the previous section.

Galliers (1999) also stressed the need for an *implementation/change management* strategy as integral to the overall IS strategizing process, and the need for *ongoing evaluation and review*. The former emphasizes the importance of managing the change processes associated with ongoing implementation of the strategy. The latter emphasizes the importance of feedback regarding the impact of past strategic decisions (unintended as well as expected outcomes) and the identification of emergent strategies (i.e., those that might "bubble up" as a result of what Ciborra (1994) calls "tinkering" and "bricolage"). Thus, importantly, the IS strategizing process is viewed as ongoing and iterative, and *not* a one-off initiative, to be undertaken periodically.

In summary, there are distinctions to be made between various commonly used terms in the IS field, and IS strategy is no exception. In Galliers's terms, IS strategy is a broad concept that encompasses the information strategy, the IT strategy, the information services strategy, and the change management and implementation strategy—as well as the assessment and ongoing review of the process outcomes, and the process itself. Collectively, these interlinked strategy components represent fundamental aspects of managing IS in organizations (see Figure 66.2). IS strategy incorporates a range of issues associated with strategy formation and formulation (i.e., the emergent as well as the deliberate), and implementation with respect to IS, and considers social as well as technological aspects. In addition, IS strategy is cross-functional since it encompasses product, process, and human resources (Lefebvre et al., 1997). From this perspective, we would argue that a business strategy is incomplete without its IS strategy.

66.3.2 Review of the Literature

The literature specifically on the processes associated with IS strategy is vast, and it covers 40 years of research, with over 470 articles in peer-reviewed journals and a number of prominent books on the subject (e.g., Blumenthal, 1969; Earl, 1988, 1989; Galliers and Leidner, 2003, 2009; King, 2009; McLean et al., 1977; Siegal, 1975; Ward and Peppard, 2002). More generally, for example, work covering related topics such as the strategic application of IT, or such topics as sourcing, would yield thousands of articles

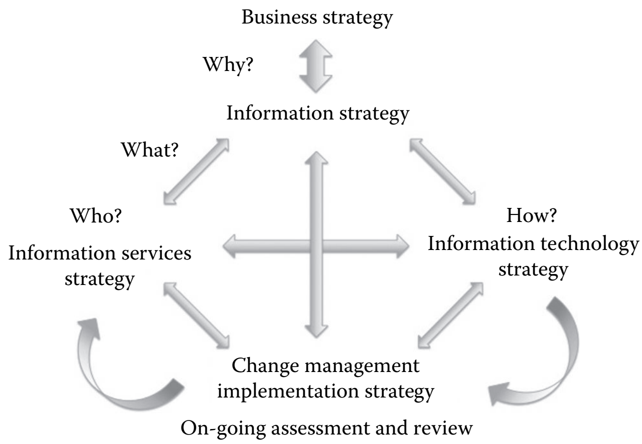

FIGURE 66.2 Components of information systems strategy. (From Galliers, R.D., in Avgerou, C., Ciborra, C., and Land, F. (Eds.), *The Social Study of Information and Communication Technology*, 2004, Oxford University Press, Oxford, U.K.)

(see, e.g., Gable, 2010, for a review of the over 300 articles that have appeared in the *Journal of Strategic Information Systems* alone in the period 1991–2009). Academic articles on IS strategy processes were particularly numerous in the 1990s (with a peak of over 30 articles in 1999), but fewer articles have appeared in recent years. However, we argue that this decline does not necessarily indicate a lack in potential areas of further research in this field, especially—as we have seen—the topic remains a prominent issue for IT executives and their business colleagues (Luftman and Ben-Zvi, 2010). Utilizing the frameworks provided by the extant literature, we derive an integrative framework to help researchers and practitioners alike to further familiarize themselves with key IS strategy themes. Here, as we have noted, we view strategy as a dynamic and ongoing process within an organization and, therefore, we consider the *strategizing process* as our particular focus of study. Through a review of extant frameworks, no single framework has been established that encapsulates all the components relevant to IS strategizing to be found in the literature. To develop such a framework, however, we began with a conceptualization that came closest to our view of strategy as a process of relevant and related activities. The input–process–output model (initially introduced by King, 1988) provided a useful building block for our synthesis, given its breadth of coverage.

66.3.3 Comprehensive IS Strategizing Framework

66.3.3.1 Input–Process–Output Models: Early Examples

The traditional IS strategy literature makes the distinction between the process and content of strategy research (Chan and Huff, 1992). While *content* research focuses on linking organizational decisions and structures to performance (or other organizational outcomes), *process* research centers on the actions and activities leading to and supporting strategy (making). The input–process–output model combines these two major components. In the model, strategy is considered to be the *output* of the strategy formulation (including development) process. In other words, it is the deliverable of the process (Ang et al., 1995; Chen et al., 2010; King, 1988; Premkumar and King, 1991; Smits et al., 1997). Furthermore, the *implementation* of IS strategy results in some type of organizational impact: such commonly considered outcomes being competitive advantage, alignment, and firm performance. The *impact* of IS strategy is included as part of the framework in a later version of the input–process–output model (e.g., Lederer and Salmela, 1996). Strategy implementation will potentially change the organizational landscape, i.e., the internal as well as the external environment of the organization. Thus, the cycle starts again with the

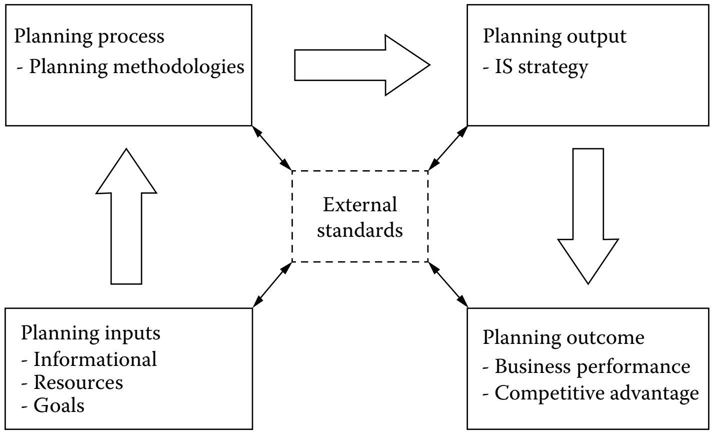

FIGURE 66.3 The input–process–output model.

internal and external environments *influencing* the strategy formulation process and the practices that are used by strategists to assess the needs and objectives of the organization. Consequently, this model incorporates considerations of such contextual factors as the planning process, strategy content, and impact of IS strategy actualization on the organization and its external environment. Figure 66.3 depicts the framework, as adapted from these earlier works.

66.3.3.2 Input–Process–Output Models: Later Extensions

Lederer and Salmela (1996) extended the earlier conceptions of the input–process–output model to provide a theory of SISP. The modified model was intended to provide a parsimonious way of identifying various strands found in the strategic IS planning literature. Specifically, Lederer and Salmela further elaborated on the constructs of the input–process–output model as they apply to SISP. First, they made a distinction among different components of planning input by considering the general context of the strategy development process, which includes elements within the organization's internal environment as well as elements beyond its control. Inputs are also the resources allocated to the planning process such as time, money, and personnel, as well as information and such intangible inputs as motivations toward and expectations of SISP. Newkirk and Lederer (2007) described SISP in terms of three IS resources planning activities: technical resources planning (i.e., planning activities associated with application software, systems software, hardware, and network communications), personnel resources planning activities (i.e., planning activities related to more people-oriented concerns such as technical training, end-user computing, facilities, and the personnel themselves), and data security planning activities (i.e., planning activities associated with protecting the organization from unwanted intrusion and recovering from such intrusions as they occur) (Doherty and Fulford, 2006).

A number of specific planning "input" factors have been mentioned in the literature. Abdul-Gader (1997) and Aladwani (2001) consider factors in the general business environment such as national and regional (e.g., socioeconomic) policies. As attention shifted to planning for inter-organizational systems (and to electronic commerce), suppliers, customers, and partner organizations were recognized as playing a more significant role in organizations' IS planning processes (Finnegan et al., 1999). Teo and King (1997) consider marketplace volatility, industry sector, competitive forces, and environmental uncertainty. Similarly, McFarlan's (1984) strategic grid represents the view that the conditions in the industry in which a firm operates largely set the scene for its IS strategy. The external conditions of a particular industry sector determine the extent of the strategic importance of IT applications (current and future) in the industry.

An explicit emphasis on the industry environment is also considered by Earl (1989), who distinguishes four types of companies in terms of their particular traits and preferences for IT. Earl finds

that in some sectors, IT is the means of delivering the goods and services in the sector. In such cases, planning for goods and services and product–market strategy formulation cannot be done without reference to IT, and planning for IT is integral to business planning. In other sectors, business strategies are dependent on IT for their implementation. In these sectors, planning for IT is a derivative of business planning. In the third type of company, IT can yield some strategic advantage and, therefore, planning is likely to include some "IT-push" characteristics, where IT is taken to the users. Last, there are companies for which IT has no strategic impact, and planning is influenced by ad hoc needs.

Additionally, Sullivan (1985) suggests a simple matrix to explain how the IS strategy environment is affected by forces both internal and external to an organization. He describes two dimensions within which an organization can consider the implications of these forces: degree of decentralization of IS control in organization (i.e., diffusion) and degree of dependence on IS of the business (i.e., infusion). Information intensity and the rate of IT change have also been considered by Benamati and Lederer (2001) and Teo and King (1997). Cegielski et al. (2005) emphasize the need for IT managers to scan emerging technologies in order to determine any potential opportunities to which these might give rise. Such studies have identified clarity of corporate strategy, IT planning resources, the available IT budget, present and future impacts of IT (Premkumar, 1992), and uncertainty concerning IS benefits and the availability of IT (Wilson, 1989), as key factors in this regard.

Arguably, business or corporate strategy is also an integral aspect of the internal IS strategy environment. The reconciliation of the IS strategy within the business strategy has found form in research on strategic IS–business *alignment* (Chan and Reich, 2007; Henderson and Venkatraman, 1993) with a clear business strategy being viewed as having a major influence on, and essential to, the IS strategy development process. Others have argued that business strategy has implications not only for the process but also on the IS strategy itself and its impact (e.g., Walsham and Waema, 1994).

Similar to the original input–process–output model, other components of the Lederer and Salmela (1996) framework include the planning process and the "output" of the process—the information plan itself. The major component of the information plan is described as a set of recommendations for new IS. Lederer and Salmela make the point that organizations often fail to develop systems identified in the information plan and, thus, they consider the plan's *implementation* to be key. This is included in their amendment to the input–process model, illustrated in Figure 66.4 and utilized in our analysis.

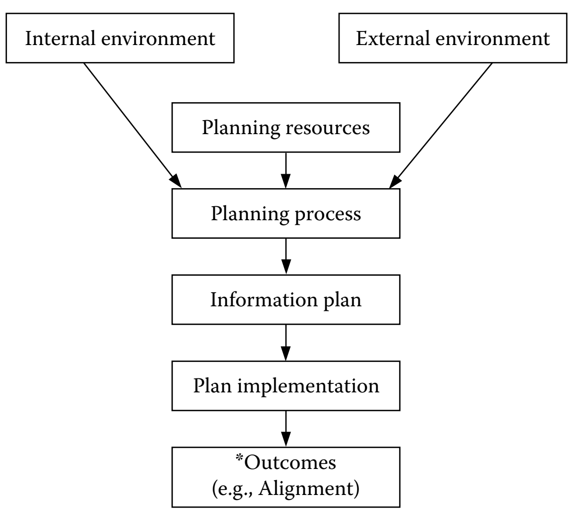

FIGURE 66.4 The Lederer and Salmela (1996, p. 240) model.

66.3.3.3 Elaboration on the Strategic Information Systems Planning Process

Early works viewed SISP as a set of defined activities but considered these activities in broad characteristics and general behaviors; rarely did the literature decompose the planning process into specific activities (McFarlan, 1971; Premkumar and King, 1991; Raghunathan and Raghunathan, 1991; Segars and Grover, 1999). Dealing with this issue, and amending the classification offered by Mentzas (1997), Brown (2004) presents six detailed phases of the planning process: preparation, organizational analysis, external environmental analysis, strategy conception, strategy formulation, and strategy implementation planning. Preparation refers to planning for IS planning process or preplanning. Organizational analysis encompasses the analysis of internal business and IS environments. Similarly, external environment analysis is the analysis of external business and IS environments. Strategy conception includes activities such as scanning the future, identifying alternative scenarios (including information flows and requirements for each), and considering the implications of each scenario (Galliers, 1992, 1993a,b). Strategy formulation is further elaborated into the formulation of agreed organizational recommendations and an associated information architecture (Galliers, 1993a,b), as well as the creation and prioritization of a portfolio of IS application developments. Finally, strategy implementation planning activities include the definition of action plan elements, follow-up, control, and an explanation of the action plan. Brown argues that these activities are necessary to ensure that the new IS are actually placed into production and used. Table 66.2 shows the process phases and the corresponding activities.

66.3.3.4 SISP Methodologies

Early SISP research provided managers with a number of methodologies (tools and techniques, rather) to apply during the planning process. Commonly, these methodologies can be divided into two broad categories: *impact* and *alignment* methodologies (Booth and Philip, 2005; Pant and Hsu, 1995, 1999; see Figure 66.5). The emphasis of impact methodologies is the gaining of competitive advantage through the use of IT—a popular theme throughout the 1980s and 1990s. Impact methodologies focused on creating and justifying innovative, value-added uses of IT. Examples of impact methodologies include critical success factors (Rockart, 1979), customer resource life cycle (Ives and Learmonth, 1984), value chain analysis (Porter, 1985), and strategic thrust analysis (Wiseman, 1985). In retrospect, the value of this kind of argumentation is debatable as much of the evidence presented was anecdotal rather than as a result of systematic studies (see, e.g., Ciborra, 1994).

TABLE 66.2 The Brown (2004, p. 29) Framework

SISP Phases	SISP Stages
Preparation	Planning for planning (pre-planning)
Organization analysis	Analysis of internal business environment
	Analysis of internal IS environment
External environment analysis	Analysis of internal business environment
	Analysis of internal IS environment
Strategy conception	Scanning the future
	Identification of alternative scenarios including information flows and requirements for each
	Scenario elaboration
Strategy formulation	Formulation of agreed organizational recommendations
	Formulation of information architecture
	Synthesis and prioritization of portfolio of information systems to be developed
Strategy implementation planning	Definition of action plan elements
	Elaboration of action plan
	Definition of follow-up and control procedures

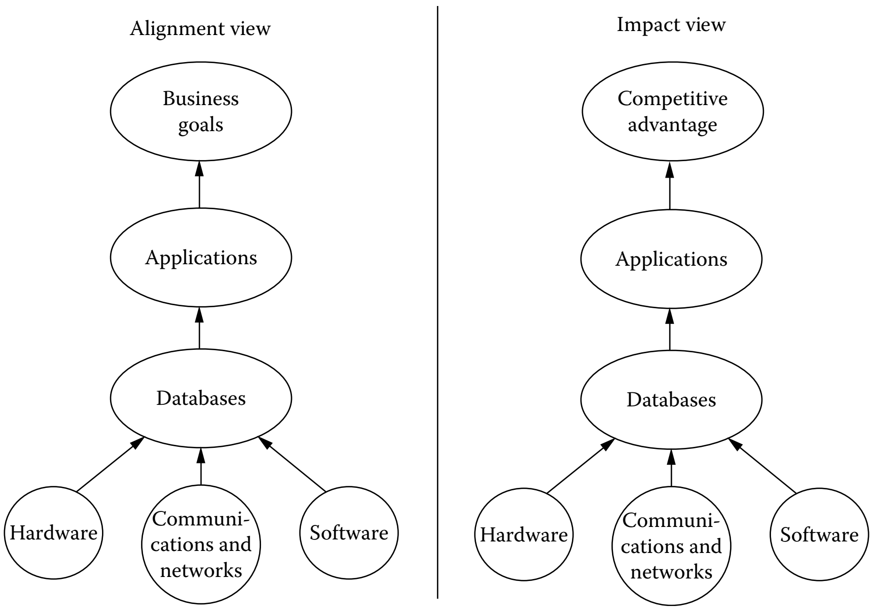

FIGURE 66.5 IS planning methodologies. (From Pant, S. and Hsu, C., Strategic information systems planning: A review, paper presented at the *International Conference on Information Resources Management Association*, Atlanta, GA, 1995, p. 5.)

The main rationale for the alignment school was to establish symbiosis between IS strategy and business objectives (Reich and Benbasat, 2000). The methodologies that fall into this category are extensive. They include Method 1 from Andersen Consulting (Lederer and Gardiner, 1992), BSP from IBM (Zachman, 1982), Information Engineering (Martin, 1989), Robert Holland's Strategic Systems Planning (Holland Systems Corporations, 1986), and Total Information Systems Management (Osterle et al., 1993). These methods take a top-down, business-led approach (Premkumar and King, 1994). Issues related to these methods include the lack of flexibility in responding to a rapidly changing business environments and concerns regarding, for example, "one size fits all" solutions (for a critique, see Galliers, 2007).

Although methodologies for SISP have taken up a large part of academic discussions (Boynton and Zmud, 1987; Lederer and Gardiner, 1992), SISP cannot, in our view, be fully understood by considering formal methods alone. It is the interaction of method applied, process followed, as well as the variety of activities and behaviors (i.e., what is termed "approaches to SISP") that characterize the planning experiences within organizations (Earl, 1993). This literature reveals a number of approaches to strategic IS planning. For example, Pyburn (1983) distinguished between the written (i.e., formal) planning system and the personal (i.e., informal) planning system. The former is a structured, top-down approach and the latter, adaptive and bottom-up. Segars et al. (1998) and Segars and Grover (1999) identified six dimensions to planning: comprehensiveness (extent of solution search), formalization (existence of rules and procedures), focus (extent of innovation versus integration), flow (top-down, bottom-up), participation (number and variety of planners), and consistency (frequency of planning). Earl (1993) identified the characteristics of SISP from other works in what is a fairly comprehensive framework (Doherty et al., 1999; Segars et al., 1998). He differentiated approaches based on nine criteria: emphasis, basis, ends, methods, nature, influencer, relationship with business strategy, priority setting, and the role of IS. Through an examination of 27 companies, Earl identified five SISP approaches: business-led (planning focused on the enterprise), method-driven (focused on the planning technique—often as provided by a vendor or consultancy, as with BSP or Method 1, for example), administrative (focused on the available

TABLE 66.3 Earl's (1993, p. 7) Typology of Approaches to SISP

	Business-Led	Method-Driven	Administrative	Technological	Organizational
Basis	Business	Technique	Resources	Model	Learning
Emphasis	Business plans	Best method	Procedure	Rigor	Partnership
Ends	Plan	Strategy	Portfolio	Architecture	Themes
Methods	Ours	Best	None	Engineering	Any way
Nature	Business	Top-down	Bottom-up	Blueprints	Interactive
Influencer	IS planner	Consultants	Committees	Method	Teams
Relation to Business Strategy	Fix points	Derive	Criteria	Objectives	Look at business
Priority Setting	The board	Method recommends	Central committee	Compromise	Emerge
IS Role	Driver	Initiator	Bureaucrat	Architect	Team member
Metaphor	It's common sense	It's good for you	Survival of the fittest	We nearly aborted it	Thinking IS all the time

resources), technological (focused on technological applications), and organizational (focused on learning). Table 66.3 summarizes these approaches, based on the nine characteristics.

An additional element of the input–process–output model was proposed by Baker (1995). Her contribution was based on systems thinking, adding a feedback loop to ensure continuous improvement in the planning process. Viewing IS strategizing as an iterative, learning process was acknowledged even in the earliest research (e.g., King and Cleland, 1975; Schwartz, 1970). Ongoing assessment and review have also been acknowledged by Galliers (2004) and Earl (1993) and are incorporated in the integrated model we propose.

No matter how detailed the input–process–output model has been extended over the years, however, it does not fully address the complex nature of the process of strategy development in practice. How organizations actually form strategy—the topic of strategy formation—has emerged as an area of intense debate within the strategy field over the years. Mintzberg (1978) points out that formulated or intended strategies may not be necessarily realized, and unplanned and unintended patterns of decisions and actions may emerge (see Figure 66.6). Concepts such as "bricolage" (Ciborra, 1994), gradual enhancement (Senn, 1992), improvisation (Galliers, 1991, 1993a,b), and "muddling through" (Lindblom, 1959) appear alongside the more formal strategy formulation approaches. Our proposed integrative model reflects the emergent nature of the IS strategizing process and distinguishes the notion of intended versus realized strategy. Intended strategy is the output or "result" of a deliberate planning process, whereas the realized strategy is the outcome of strategy implementation process during which some of the intended strategy may be realized while other aspects may not. The realized strategy also reflects some of the emergent strategies that materialize during the formation process.

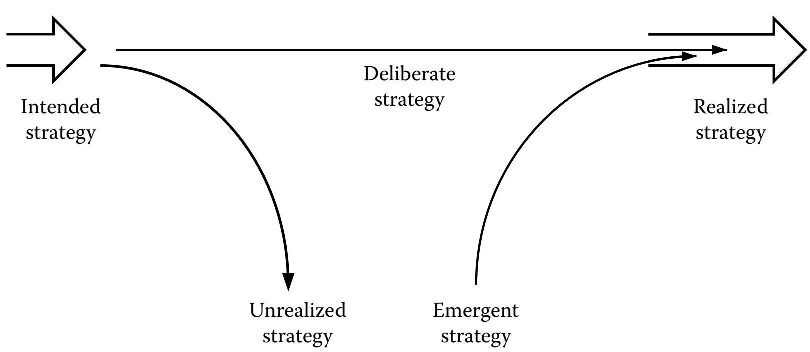

FIGURE 66.6 The Mintzberg (1978, p. 945) model.

The distinction between emergent and deliberate strategies appears in other relevant frameworks. In particular, Whittington (2002) proposes four generic approaches to strategy that differ along two dimensions: the outcomes of strategy and the processes by which it is made. The process dimension reflects whether the strategy is the product of deliberate planning or the result of emergence, accident, muddle, or inertia. The outcome dimension indicates the degree to which the strategy produces unitary (e.g., profit maximization) outcomes, or allows for consideration of alternative, pluralistic outcomes. For example, Segars and Grover (1998) suggest four dimensions of SISP success outcome: alignment (the linkage of the IS strategy with business strategy), analysis (the effort by IS planners to understand the internal process, procedures, technologies), cooperation (the agreement among IS planners concerning priorities, implementation schedules, and managerial responsibilities), and improvement in capabilities (the enhancement in SISP capabilities as a result of organizational learning). Similarly, King (1988) argues that the measurement of SISP impact should be multidimensional, and based on both judgmental and objective assessments. Dimensions proposed by King include the effectiveness of the strategy approach, its relative worth, the role and impact of IS strategy, the performance of IS plans, the relative efficiency of the strategy process, the adequacy of resources made available, and strategic congruence. The outcome of an IS strategizing process thus presents an additional consideration in the literature as it expands the scope of the formation process.

In summary, the proposed framework arising from this literature review includes the contextual dimension of IS strategizing (ISS), which comprises the external as well as the internal environment (see Figure 66.7), and attempts to be more holistic in nature than those that are often presented in existing research. Resources and capabilities are an important component of ISS and are, therefore, explicitly highlighted in the framework. The resource-based view (Barney, 1991; Rumelt, 1984; Wernerfelt, 1984) and the capabilities view (Peppard and Ward, 2004) are gaining increased attention, and they are used to explain the increased complexity of causal relations between IS strategy and firm performance. We have also included ongoing assessment, review, and feedback processes (e.g., Baker, 1995; Earl, 1993; Galliers, 2004) as the link between content and the process of strategizing. Additionally, we incorporate the kind of thinking that Brown (2004) introduces in illustrating specific phases in the SIS process.

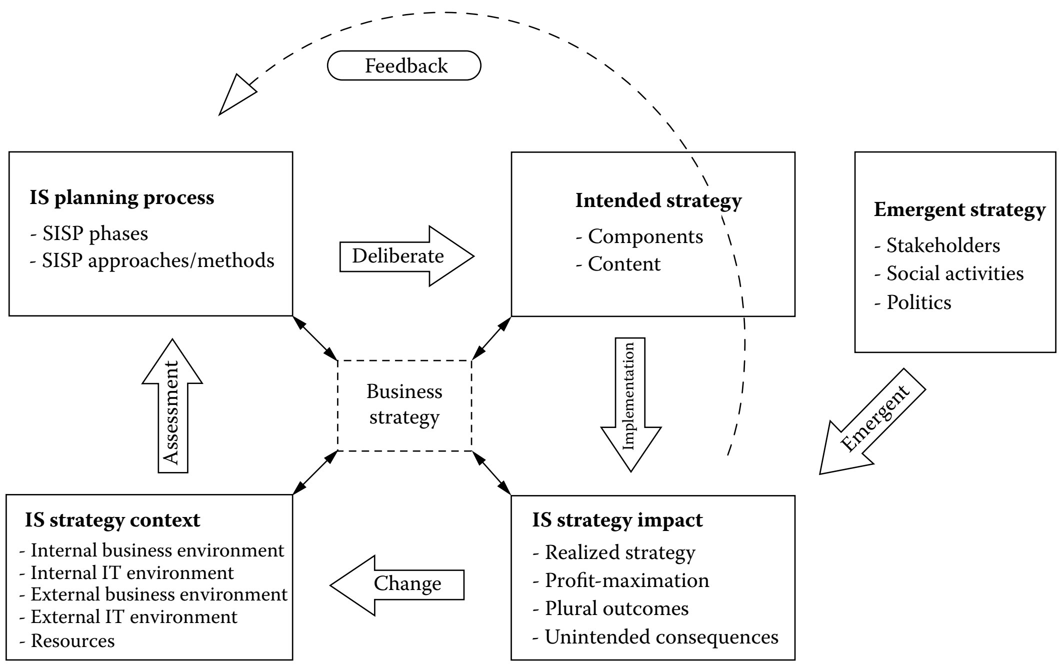

FIGURE 66.7 The proposed framework for IS strategizing.

Galliers (2004) provides components of IS strategy that might be addressed by an organization and are considered as the output of the planning process. These components might guide planners in the areas of strategy they need to plan for in their strategy development process.

The realized strategy is an outcome of the emergent process as well as a deliberate plan (Mintzberg, 1978), so the emergent strategy is incorporated in the framework as a topic that explores the unintended/unplanned social activities of strategy formation. Finally, profit maximization is often seen as the natural outcome of strategy making, but this unitary view is amended by the pluralistic view proposed by Whittington (2002), where strategists might have other interests or objectives than profit.

It is important to note that the IS strategizing "process" does not always occur sequentially in an organization, and there will always be overlap across various components that have been incorporated in the framework. In addition, different businesses and functions within an organization may be involved at different stages of the process. The framework is a conceptual tool—a sense-making device in Weick's (1990) terms—aimed at helping practitioners and researchers in understanding better the various areas encompassing this complex process and particularly those that need attention or further research.

Researchers and practitioners alike can use this framework to assess, in a comprehensive manner, the process of IS strategizing in organizations. For example, the framework points to the importance of resources consumed by the strategizing process. Justification of the use of such resources is critical to organizational survival during downturns because the resources allocated to planning activities are often substantially reduced during such difficult times (King, 1988). With respect to the intended strategy component of the IS strategizing process, a general question that might need to be considered is whether the plan in fact guides the strategic direction for the role of IS in the organization. The impact of IS strategy might be difficult to assess, and the framework suggests evaluation based on multiple outcome parameters. This multidimensionality further suggests the involvement of multiple stakeholders. The notion of "second-order" feedback incorporated in the framework may be applied to the assessment of the IS strategizing process by, for example, determining whether the process has any "self-correcting" characteristics (King, 1988).

66.4 Impact on Practice

There has been a gap between academic discussion on IS strategy and how IS strategy has been perceived in practice. Practitioners are mostly concerned with the technical dimensions of IS strategy, such as decisions on IT infrastructure, architecture, and standards. While the academic debate has been primarily on IT-based competitive advantages and has stressed the role of information as a strategic resource, practitioner conferences and magazines have mainly discussed technology developments (e.g., cloud computing, service-oriented architecture, software as a service, Web 2.0) and new types of applications (e.g., customer relationship management, social software, business intelligence) (Teubner and Mocker, 2008).

A significant proportion of the literature on IS strategizing often presents the process as being problem-based, with a linear progression from the problem toward a desired outcome (Horton, 2003). In addition, it is often viewed as a formal, rational planning activity (Galliers, 1991; Knights and Murray, 1994; Scott-Morton, 1988; Waema and Walsham, 1990; Walsham, 1993). There are a range of noted assumptions underpinning this perspective of IS strategizing such as that social relations are cooperative, resources are available as required, objectives are known, people will be able to develop necessary aspects of strategy in an objective manner, there is a clear appreciation and understanding of cause–effect relationships, and there is enough information to enable the required activities to operate (Kling, 1987; Waema and Walsham, 1990). We argue that this represents an idealized, superficial, and limited view of what has been found in practice and that such formal rational approaches to IS strategy formulation have rightly been criticized as "unrepresentative of organizational reality and generally simplistic" (Waema and Walsham, 1990, p. 30).

During the last decade, researchers have returned to questioning the underlying mechanisms explaining IT/IS-induced competitive advantage. The IS capability view (Peppard and Ward, 2004) and the study of the barriers to the erosion of competitive advantage (Piccoli and Ives, 2005) are good examples of such developments. A number of studies have addressed the *means* and *ends* of IS value creation, but, as with studies concentrating on maintaining IT competitive advantage, there is a paucity of research providing rigorous tests of theoretical propositions, with cause–effect relationships of how IS value is realized being inadequately explained.

The IS capability view concentrates on explaining the "whys?" of IS value creation and suggests, in Peppard and Ward's (2004, p. 188) words, that "the strategic management of IS is about developing IS competencies." The IS capability view guides practitioners to focus on how IS/IT is managed and used and has clear implications for both IS strategic planning theories and practice. The IS strategy impact is explained by more explicit cause–effect relationships, thereby helping organizations to better understand and justify the effects of IS developments. Compared to traditional technological developments, by concentrating on competency development, organizations might be less vulnerable to losing their competitive edge, given that such competencies are considerably harder to imitate or substitute than technological assets. Similarly, IS strategy content will be shifted from technology or alignment to planning for the competencies needed to exploit IS/IT developments. Though the Peppard and Ward (2004) article seems to be one of the most frequently cited works in the IS strategy literature concerning IS capabilities, a decade earlier, several authors contributed to the topic and even adopted the capability view as their "IS strategic platform" to build on (e.g., Ross et al., 1996).

By 2010, the number of articles concerning IS capabilities showed remarkable growth, clearly indicating the shift in IS strategy conceptualization toward more capability-based thinking. The extent to which such thinking is applied in practice remains debatable, but having said that, such centers as MIT's Center for Information Systems Research (CISR) in the United States and Cranfield's IT Leadership Programme in the United Kingdom have a practical orientation, given the financial backing they receive from corporate clients.

66.5 Research Issues

In general, IS strategy implementation has received by far the least attention in the IS strategizing discussion (Teubner and Mocker, 2008). Having said that, a number of scholars have acknowledged the significance of strategy implementation. For example, Ward and Peppard (2002, pp. 125–126) point out that "Despite an understanding of the importance of strategic planning for IS, in the past decade many organizations have developed perfectly sensible IS strategies that have been left to gather dust, or have been implemented in a half-hearted manner …" A survey by Lederer and Sethi (1988) found that after about 2 years into the planning horizon, less than one-fourth of the projects that were defined in the IS strategies had been initiated. A study of Norwegian organizations revealed that, after 5 years, only 42% of the projects that were defined in the strategy had been implemented (Gottschalk, 1999). Stricter implementation measures such as completion on time or realization of intended benefits (Earl, 1993) result in even smaller implementation rates (Gottschalk, 1999).

Smirchich and Stubbart (1985, p. 724) suggest that the problems of strategy implementation stem from the "field's inattention to the fundamentally social nature of the strategy formation and organization processes." Given the vast amount of research that explains different components of IS strategy and the strategizing process, it is perhaps surprising how little literature considers strategizing as a social activity. Only a small portion of the extant research has studied the key figures of the IS strategizing process, such as the chief information officer (CIO), and even fewer publications investigate the activities organizational members engage in during the IS strategy-making process. For example, our literature review of IS strategizing research has identified less than 5% of the articles reviewed considering the role CIOs play in the IS strategizing process.

Strategy is formed by highly skilled workers, and it is important to understand what skills are required for this work, how to acquire these skills, and what the common behaviors and techniques of strategizing actually take place (Whittington, 2003). The limited amount of research that considers the structure, rules, and processes of the IT function, as well as IT personnel requirements, IT skills, and IT personal development, has been mostly conceptual and has provided little more than anecdotal evidence (e.g., Agarwal and Sambamurthy, 2002). More research should focus on how the practitioners of strategy actually act and interact in the process of strategizing (Jarzabkowski, 2004; Whittington, 1996).*

The current economic environment is moving rapidly toward open markets, mobile labor, and information abundance (Johnson et al., 2003). The ease of obtaining resources, falling barrier to market entry, and strategic imitation creates a precarious foundation for a competitive advantage (Barney, 1991). As a result, sustainable advantage must lie in microassets that are hard to discern, imitate, and obtain. There is also a shift to a more "hypercompetitive" environment, in which speed, revelation, and innovation are the bases for competitive advantage. This requires organizational decentralization and more continuous, adaptive, and innovative processes (Brown and Eisenhardt, 1997) in strategy making. More people are involved in the process and research needs to understand their role in the strategizing. As a result, the activities of managers—what they do, how and why they do it—are increasingly becoming central to the strategy debate (Johnson et al., 2003).

66.6 Summary

Considerations of IS strategizing in organizations have developed from the isolated, to the more aligned, and then to the impact modes of planning. The aim of this chapter has been to provide something of a synthesis of the research literature on the concept of IS strategizing process. In doing so, we have taken a broader perspective on IS strategizing and have emphasized the dynamic, continuous, iterative, and interactive nature of the strategizing process (e.g., Auer and Reponen, 1997; Baker, 1995; Ciborra, 1997; Earl, 1993; Reponen, 1993; Salmela et al., 2000). We have described the strategizing process as being quintessentially social—one that includes negotiation for allocation of organizations' resources, requires commitment and support from top management, and involves multiple stakeholders (Earl, 1993). In this regard, we argue that IS strategizing has—or should—become even more inseparable from strategic business planning. Any strategic change in IS requires increasing change in business operations and processes, and thus IS strategizing and strategy implementation require organization-level attention and capabilities well beyond the traditional boundaries of IS. We expect future research in IS strategy to find new ways to connect—and unpack—these already heavily interconnected key aspects of strategic business planning and strategic IS planning—topics that have for too long been considered by their respective academies as being their own "territory." Research in IS capabilities has already taken some steps in this direction, but more is required.

Glossary

Bottom-up planning: An IS planning view in which the driver for planning comes from technological opportunities.

Capabilities: A firm's capacity to acquire, deploy, and leverage resources, usually in combination, using organizational structures, processes, routines, learned and stable activities, and/or behavioral orientation to effect a desired end.

Change management strategy: A component of IS strategy that emphasizes the importance of feedback regarding the impact of past strategic decisions (unintended as well as expected outcomes) and the identification of emergent strategies.

---

* The issue has already recognized by some notable IS journals. For example, at the time of writing, the *Journal of Strategic Information Systems* is planning a special issue on IS strategy and strategizing from a practice perspective.

Data processing: An early (pre) era of IS strategizing in which the business objective was to automate information-based processes to improve operational competence by reducing data processing costs and consequently achieve business efficiency. IS operations and the possible IS plan tended to be isolated from the business of the organization.

Dynamic capabilities: Structures, processes, routines, learned and stable activities, and/or behavioral orientation that help organizations change by creating an ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments.

Goal seeking: An IS planning view in which the objective and focus are mainly on proactive future effectiveness of IS and delivering new opportunities for business operations.

Implementation strategy: A component of IS strategy that emphasizes the importance of managing the change processes associated with ongoing implementation of the strategy.

Information services strategy/information management strategy: Focuses on policy issues regarding the organization of information services (and capabilities), including sourcing decisions—"the organizational arrangements for the provision of IS-related services." Answers mainly "who?" questions: Who is needed to facilitate and enable the strategy to be developed and implemented? Such questions include considerations of the structure, roles, and processes of the IT function, but also include human resources issues such as IT personnel requirements and choices between the internal service provision.

Information strategy: Focuses on identifying the information that could question taken-for-granted assumptions on which the business strategy is based, as well as providing the information required by the business strategy. Thus, an information strategy is the glue between the business strategy and the IS strategy. It tends to answer questions such as, "What is the information required to support primary tasks, or key goals, of the organization strategy?" and "Where can this be obtained?" The information strategy also questions the business strategy by attempting to answer the "why" questions—"Why might this particular strategy be chosen over any other?"

IS (information systems): IS as a whole is a sociotechnical concept, including not only the technical IT perspective, but also the business processes, social processes, users, and connections to internal and external environment that affect the operation of the systems; "everything that the systems are made of."

IS capabilities: A firm's ability to acquire, deploy, and leverage its IT resources (human as well as technical) to shape and support its business strategies and value chain activities.

IS dynamic capabilities: Dynamic capabilities (see the previous term) related to the IS operations of the organization.

IS strategic planning: An overall term describing the efforts and resources to plan for IS operations of the organization and to create an IS strategy. It should be considered an ongoing process rather than a one-off effort.

IS strategizing/IS strategizing process: The process and details of IS strategic planning, including the objectives, resources, and efforts to keep up a strategically alert cognition for IS and the organizational requirements to implement the IS strategy. An inherent connection to business objectives and strategizing is a crucial part of IS strategizing, and vice versa.

IS strategy: Can be considered the developmental path that needs to be taken to achieve the business objectives related to IS, considering both deliberate and emergent sides of the IS strategy. IS strategy is a cross-functional overall term that encompasses, e.g., product, process, human resources, and several interlinked components such as information strategy, information services strategy, implementation, and change management strategy as well as the strategizing process (see later). Recent developments have taken a more holistic view to what should be taken into account in IS strategy, including IS capabilities (see later).

Issue-based: An IS planning view in which the objective and focus are mainly on reactive effectiveness of IS.

IT (information technology): A term describing the technical/architectural aspects of information systems, mainly the hardware, software, and their physical connections.

IT strategy: The strategic plan for IT (as described earlier), mainly concentrating on technical effectiveness. Concerned with alternative technological solutions (alternative “hows”) to support the “what” of business needs.

MIS (management information systems): Another era of IS strategizing in which the objective, in addition to operation efficiency, was to create ways of organizing and delivering information to improve management effectiveness. Also the era when the need for IS strategizing became apparent and focus on IS planning efforts gained increased attention.

RBV (Resource-based view): A theoretical perspective explaining the competitive edge of a company with valuable, rare, inimitable, and non-substitutable (the so-called VRIN) resources and capabilities.

SIS (strategic information systems): The SI strategizing era, with a proactive stance and objective to change the nature or conduct of business to improve the competitiveness of the company.

SISP (strategic information systems planning): The process of identifying a portfolio of computer-based applications that will assist an organization in executing its business plans and realizing its business goals.

Top-down planning: An IS planning view in which the driver for planning comes from holistic business requirements of the organization.

Information Technology and Organizational Structure

M. Lynne Markus
Bentley University

67.1 Introduction

The first commercial uses of computers—for applications such as accounting, insurance claims processing, and airline reservations—date from the early 1950s. It was not long afterward that futurists began to speculate about the effects of computer use on the form and functioning of organizations. In 1958, Leavitt and Whisler—coiners of the term "information technology"—predicted that IT would have "definite and far-reaching impact on managerial organization" in large- and medium-sized business firms (Leavitt and Whisler, 1958, p. 41).

Leavitt and Whisler made four specific predictions. First, occupational specialization would increase: Business planning work would be taken from mid-level line managers and given to a new class of specialists such as operations researchers, who would develop tools and standardized routines for their work. Second, large organizations would re-centralize, with top managers taking over much of the planning and innovating work that they had formerly delegated to middle managers. Third, while the new specialist functions would increase in status and compensation, many middle management jobs would be downgraded or eliminated; instead of the traditional pyramid shape, the organization of the future might look more like "a football [the top staff organization] balanced on the point of a church bell" (p. 47). Fourth, the invisible line separating the top of the organization and the middle would become more distinct and impenetrable.

For years, these hypotheses about the effects of IT on organizational structure appeared to be as infamously wrong as Thomas Watson's (then IBM's Chairman) 1943 prediction about the world market for computers ("maybe five"). But 30 years later, scholars called Leavitt and Whisler's predictions

"downright visionary" (Applegate et al. 1991, p. 128). However, the futurists of the late 1980s noted effects of IT on organizational structure that Leavitt and Whisler had not envisioned; they argued that the adoption of microcomputers would enable increased *de*centralization of decision making at the same time that IT also enabled downsizing, restructuring, and improved centralized control. These paradoxical impacts of IT would make large organizations as flexible, dynamic, and innovative as small firms (Applegate et al., 1991).

This, in a nutshell, is the debate over the impacts of IT on organizational structure, which stimulated much empirical research and theorizing in a number of fields and subfields, including the social issues and impacts of computing, information systems, organization theory, organizational communication, strategic management, international business, sociology, and economics. Although the theories, evidence, and implications are all contested, research about *whether and how* IT affects organizational structure is important for theoretical and practical reasons.

Theoretically, the concept of organizational structure—loosely, the anatomy of an organization, its skeleton and organs, as opposed to its physiology or metabolism—is central to a number of prominent organizational theories such as the information processing theory of organizations and the strategy–structure–performance paradigm. Although some theorists argue that organizational culture and processes are more important for organizational performance than organizational structure is, others counter that organizational structure shapes (but does not determine) information flows and pathways of organizational communication and helps focus the attention of managers, thus influencing organizational behavior. From this point of view, the hypothesis that IT affects organizational structure is important, because it establishes IT as a key factor in organizational performance. In addition, research about the effects of IT on organizational structure is a prominent manifestation of ongoing academic debates about technological determinism versus idealism, that is, about whether and how human behavior is affected by the material aspects of the world versus by people's ideas and beliefs about the world.

Practically, research and theorizing about IT's effects on organizational structure is important for at least two reasons. First, this body of knowledge suggests that, in order to perform well, organizations need information systems that match their organizational structures and strategies. Briefly, organizational structures have been observed to vary not only in degree (e.g., how centralized they are) but also in type (e.g., whether they are organized according to customers, products, or both) even among apparently similar firms (e.g., consumer product manufacturers). A line of argument uniting the strategy–structure–performance paradigm with the IT-affects-organizational-structure hypothesis implies that effective organizations will employ information systems with features that are closely aligned with their structures and strategies. For example, Croteau and Bergeron (2001) found that organizations with information systems matched to their business strategies had higher performance than organizations without such a match. Similarly, Strikwerda and Stoelhorst (2009) observed that organizations with multidimensional structures (i.e., organizations structured to emphasize customers, products, and functions simultaneously) needed to, and typically did, employ centralized information systems that can identify and summarize transactions and forecasts in flexible combinations of customers, products, and functions, whereas organizations with multidivisional structures (i.e., decentralized organizations with business units for particular product–market combinations) did not require or employ such systems. Conversely, the body of knowledge on IT and organizational structure suggests that organizations with information system features inappropriate for their strategies or structures will fail to accomplish their objectives and will perform poorly (Bergeron et al., 2004; Chan and Reich, 2007a,b; Soh et al., 2000; Strong and Volkoff, 2010).

A second practical implication of research on IT and organizational structure concerns the provisions that large and complex organizations make for managing their IT. The body of knowledge on IT and organizational structure suggests that effective strategies *for managing IT in organizations* will vary with organizational structures. Even if an organization relies heavily on external IT service providers, its managers face numerous choices about how to structure IT support. For instance, should they manage IT centrally or allow each major organizational subunit to manage its own IT? Application of research

and theorizing on IT and organizational structure suggests that structure should be a major consideration in the design of IT management arrangements.

This chapter aims to survey key concepts, theories, findings, and implications of research on IT and organizational structure. Section 67.2 examines how organizational structure has been conceptualized and discusses findings about the relationship between IT and organizational structure. Section 67.3 elaborates on the practical implications of this body of knowledge. Section 67.4 explores promising directions for future research on IT and organizational structure.

67.2 Underlying Principles

Organizational structure has been studied over many years by scholars in several fields—including sociology, economics, organization theory, business history, strategic management, and organizational communication and information systems—with varied theoretical interests and research questions. Consequently, any attempt to review this vast literature will necessarily oversimplify and risk offending through its categorizations, (mis)characterizations, and omissions. That said, it is important to have at least a cursory appreciation for the ways that organizational structure has been understood before considering its possible relationships with information technology.

67.2.1 Organization Structure: Definitions, Theories, and Questions

Most theories of organizational structure trace their roots to Max Weber's (1864–1920) theory of bureaucracy, which emphasized a hierarchy of authority, written rules, and officials with expert training and career advancement based on technical qualifications. Among other foundational scholars were Nobel laureate Herbert Simon (1916–2001), a major contributor to computer science whose 1947 *Administrative Behavior* became the foundation of American administrative and management sciences, and sociologist Peter M. Blau (1918–2002), whose major empirical studies of organizational structure and technology extended Weber's theory of bureaucracy and its role in society. Research based on the work of these seminal thinkers went in two general directions—focusing on structural characteristics or on configurations of design characteristics—although there was considerable overlap and mutual influence between them.

67.2.1.1 Organizational Characteristics

Shortly after World War II, scholars at the Tavistock Institute in the United Kingdom observed that formal and informal work group structure varied with the nature of coal-mining technology. Others generalized this "sociotechnical systems theory": Woodward (1958) concluded that differences in production technology (e.g., mass production versus process control technology) offered the best explanation for differences in organizational structure. In an influential program of empirical research in the 1960s, known as the Aston studies (e.g., Hickson et al., 1969), researchers focused on dimensions of organizational structure such as role specialization, standardization of procedures, centralization of decision making, and direct supervision versus impersonal control (i.e., written procedures). One finding of the Aston studies was that organizational structure was related to organizational size; larger organizations were more specialized, more formalized, more standardized, but less centralized. A second key conclusion was that of a compensatory relationship between decentralization (delegation of decision making) and structuring in the form of bureaucratic rules and procedures. In other words, organizations can "centralize" decision making either by means of direct supervision or by *de*centralizing decision-making authority within the limits set by "impersonal" rules (Donaldson et al., 1975).

Aston researchers also found that the effects of production technology on organization structure were moderated by organizational size, contradicting Woodward's main conclusion. (Research about the relationship between organizational size and structure is relevant to questions about IT, because

one of the major ways in which IT is said to affect organizations is by reducing organizational size; for example, automation replaces workers, enabling downsizing.) Research by Blau and his colleagues (Blau, 1970; Blau et al., 1976) generally confirmed the Aston researchers' findings about the importance of organizational size and the role of technology in organizational structure. From a large-scale empirical study of Employment Security Offices in the United States, Blau (1970) concluded that as organizations increased in size, they increased in differentiation (number of different types of positions), although the rate of increase in differentiation decreased with size. He also found that the size of the administrative component of organizations (the fraction of employees not directly engaged in production) decreased as organizational size increased. In a study of both production technology and computerization of administrative support functions in U.S. manufacturing plants, Blau et al. (1976) found that, whereas mass production technology routinized work and simplified administrative procedures and thereby promoted decentralization, process control technology (e.g., chemical processing) reversed those trends, leading to the development of specialized skills, "a complex administrative apparatus," and a more centralized structure (p. 24).

Some subsequent research has aimed to analyze, model, and classify organizations with detailed attention to their structural characteristics (Burton et al., 2006; McKelvey, 1982). Generally, however, most other organizational scholars have tended to focus less on the fine-grained structural characteristics of organizations and more on a few ideal organizational types, often called configurations or archetypes (Miles and Snow, 1996; Mintzberg, 1979, 1983). Organizational configurations are conceptualized as bundles of interrelated characteristics (Meyer et al., 1993). In addition to structural characteristics, organizational configurations often include nonstructural elements such as organizational strategies, organizational environments, and organizational cultures or informal interaction patterns. Researchers often use the terms "organizational design" or "organizational form" instead of "organizational structure," when they want to refer to configurations of structural and nonstructural characteristics.

67.2.1.2 Organizational Configurations

At about the same time as the Aston studies, Chandler (1962) published a highly influential historical study of structural change in leading American companies such as Standard Oil, General Motors, DuPont, and Sears Roebuck. Whereas Blau was interested in the interplay between the formal structural characteristics and informal patterns of communication and social interaction within organizations, Chandler was interested in differences across organizational configurations or forms. Chandler used the term "organizational structure," but he defined it much more broadly than scholars like Blau. Chandler included in his notion of structure both formal and informal lines of authority and communication, as well as the information and data that flowed through those lines (Whittington, 2002). As a result, Chandler can be considered a configuration theorist.

Chandler documented and offered a historical explanation for the emergence, around 1920, of a new organizational form, called the multidivisional organization. The multidivisional form represented a change in the "basis of organization" in large enterprises. Loosely put, "basis of organization" refers to the boxes on an organizational chart at the level just below that of the chief executive. Prior to the 1920s, most organizations of any size were structured on the basis of "functions," that is, units devoted to activities such as marketing, sales, engineering, and manufacturing (as well as support functions, such as accounting/finance, human resources, and—much more recently—IT). This form of organization is variously called "centralized," "functional," or "unitary" (or "U-form"). The U-form is understood as a "centralized" organizational form, because, for any decision that cuts across functions (such as a decision about a new product to be offered or a new market to be entered), no one functional unit head is able to make a good decision without input from other functional unit heads, and therefore, the final decision must be made at the top. By contrast, M-form (multidivisional) organizations are structured on the basis of "business units," which in the classic definition (Porter, 1980) are organizational units

with profit-and-loss responsibility for particular product–market combinations, such as “Asia-Pacific semiconductors” or “International chemicals” or “North American generic drugs.” The M-form is understood to be a “decentralized” organizational form. The reason is that, whereas in the U-form chief executives make key decisions about products and markets, in the M-form these decisions are made by business unit managers that report to chief executives. In other words, chief executives delegate some decisions to business unit heads. However, top managers in M-forms generally retain cross-business unit decisions such as which product–markets to enter and how much to invest in each.

Chandler argued that organizations began adopting decentralized forms of organization in the 1920s for two reasons. First, improvements in transportation and communication technology (railroads and telegraphs) had enabled organizations to enter new markets. Second, increased scale of operations and exposure to new markets encouraged organizations to develop and offer new products and services (Chandler, 1962). In the field of strategic management, both developments are understood as strategies of diversification, and these strategies are believed to strain the decision-making capacity of top managers. Spurred by the problems created by diversification, in Chandler’s analysis, organizations responded by innovating in their administrative structures and procedures. By decentralizing their structures, large diversified organizations were able to improve their performance.

Chandler’s pioneering work stimulated numerous streams of research relevant to the question of IT’s relationship with organizational structure. One influence can be seen in the development of the information processing theory of organizations (also powerfully shaped by the work of Herbert Simon and his colleagues), of which Jay Galbraith is a leading proponent (Galbraith, 1977). According to information processing theory, organizational designs (structures plus lateral relationships, including informal ones) are seen as tools for channeling information, communication, and managerial attention. Galbraith is notable for his highly naturalistic, yet holistic, characterizations of organizational design in terms of their primary and secondary “bases of organization.” His writings are filled with detailed organizational charts. By looking at the allocation of responsibilities to the most senior executives in these organizational charts, one can easily see each company’s strategic priorities.

Galbraith is one of the several prominent authors who studied the internationalization of business and the evolution of multinational enterprises. Other international business scholars such as Bartlett and Ghoshal (1989) and Goold and Campbell (2002) have studied the changing organizational forms of companies with worldwide operations. Today, some observers (Strikwerda and Stoelhorst, 2009) posit the emergence of a new form, the “multidimensional organization,” with distinctly different characteristics and management systems than M-form organizations.

Perhaps the most influential program of research stimulated by Chandler’s work has been Oliver Williamson’s (1985) theory of markets and hierarchies, also known under the shorthand of organizational economics. Williamson viewed the M-form as the most significant organizational innovation of the twentieth century (King, 2011) and developed a theory to explain how, when, and why firms (hierarchical authority systems) differ from, and emerge instead of, arm’s length market arrangements. This theory was subsequently expanded to accommodate hybrid or “network” organizational forms involving close partnerships among organizations, such as joint ventures and major “outsourcing” relationships (e.g., contract manufacturing). Theory and empirical research on networked and virtual organizations was, of course, fueled by growing awareness of the pervasiveness of organizational IT.

The many empirical studies in the strategy–structure–performance paradigm of the strategic management field are among the legacy of Chandler’s historical research. Although empirical results in this tradition have been mixed (Whittington, 2002), almost all subsequent research on organizational design and new organizational forms owes a debt to Chandler’s influence.

67.2.1.3 Summary: Organizational Structures and Configurations

Simplifying greatly, in the years leading up to Leavitt and Whisler’s predictions about the effects of IT on organizational structure, some scholars had attempted to explain the detailed formal structural

characteristics of organizations and to explore their interactions with informal patterns of behavior and communication. Researchers in this tradition highlighted organizational size and production technology as important determinants of organizational structure. Other scholars tended to focus on organization "designs" or "forms," that is, packages or configurations of elements including structure, strategy, environment, and informal social interactions that commonly occur together. Those researchers emphasized the emergence of new organizational forms and the consequences of organizational forms for performance. Both research streams continue to evolve, influencing research on IT and organizational structure, although the second stream is more active today. The study of organizations includes many other intellectual traditions in addition to the ones reviewed here (including a few discussed later), but those two are the most relevant for understanding research on the links between IT and organizational structure, described more fully next.

67.2.2 Links between IT and Organizational Structure

One of the most interesting aspects of the research on IT and organizational structure is that much theory and research suggest that IT has "dual outcomes" (Pool, 1978), that is, apparently opposite effects nearly simultaneously or coterminously. For example, use of the telephone was said to have promoted the construction of skyscrapers, leading to increased urban density, at the same time that it contributed to urban sprawl (Pool, 1983). Similarly, IT has been argued and found (1) to promote both centralization and decentralization of decision making, (2) to lead both to smaller and larger organizations, and (3) to foster both new horizontal organizational forms and new bureaucratic forms of organization. Each of these three main areas of research is discussed briefly in the following.

67.2.2.1 IT and Centralization/Decentralization

Much of the earliest work on IT and organizational structure concerned structural characteristics. The term "centralization" has multiple meanings (King, 1983), many of which are relevant here. First, the descriptor "centralized" is used by some scholars to refer to a particular organizational design or form—the functional or U-form discussed earlier. Section 67.2.2.3 summarizes literature related to IT and new organizational forms.

A second meaning of the term centralization concerns physical location of organizational activities—concentrated in one geographic location versus dispersed in space and time. Theoretical arguments and empirical examples can be found to link information and communication technology to either increased geographic concentration or greater geographic dispersion. For instance, through the use of telecommunications, some organizations have geographically (and structurally) concentrated organizational support services such as accounting, human resources management, and IT help desks into regional "shared services centers," eliminating the smaller local groups of support personnel dispersed among individual offices or factories (Sia et al., 2010). At the same time, IT is also being used to enable geographically and organizationally dispersed individuals to work together as if they shared geographic location and company affiliation (Ahuja and Carley, 1998; Argyres, 1999; Majchrzak et al., 2000).

Most commonly, the term centralization is used to refer to the level in an organization at which decisions are made. When decisions are made at the top, decision making is labeled centralized; when decision making is delegated to business unit managers or below, the organization is referred to as decentralized. As noted in the introduction to this chapter, Leavitt and Whisler (1958) argued that IT would increase centralization of decision making. Their rationale was that managers prefer centralization, because it gives them greater control over the people and processes of the organization. They decentralize only reluctantly, because in large diversified organizations they cannot be well enough informed about local conditions to make good decisions. Growing computerization increased top managers' ability to make more and better decisions themselves; consequently, use of IT was expected to promote re-centralization (Leavitt and Whisler, 1958).

Computerization was seen as a key tool in the strategy of top-down administrative control, because it gave mangers the ability to formalize tasks and monitor the outcomes of decisions by lower-level staff (Blau and Schoenherr, 1971). Some empirical research (Blau et al., 1976; Whisler, 1970) found support for the centralizing effects of IT (cf. Whisler, 1970). For instance, Blau et al. (1976) found that the use of computers for administrative support generally continued the centralizing trend associated with advanced process control technology (versus mass production).

However, almost immediately, researchers advanced arguments for the "dual" or opposite effect. Klatzky (1970) argued that the analyses leading to routine decisions would be programmed into computer code, giving senior managers enough confidence to delegate responsibility for these areas to lower levels of the organization and allowing senior executives to concentrate on more strategic and less programmable decisions. Blau et al. (1976) found some evidence of IT-related decentralization, as well as centralization, in New Jersey manufacturing plants: "In contrast to the centralizing influence of an advanced production technology [e.g., process control], an in-house computer to automate support functions promotes decentralization, though primarily in the form of granting autonomy to the plant manager [but no lower]" (p. 35).

Of course, one has to ask whether the apparent decentralizing effects of IT constitute true delegation and autonomy for lower-level employees. As noted by Robey (1981) in an early review of IT and organizational structure research, "what appears to be greater decentralization may simply entail the delegation of more routine decisions whose outcomes are more closely controlled" (p. 681). Just as Aston school researchers had concluded that organizations can exert central control both by top-down supervision or by the application of impersonal rules (Donaldson et al., 1975), so it also seems that IT may be used to support greater *centralization* in either way: by enhancing the ability of superiors to make decisions themselves or by enabling subordinates to make decisions within carefully circumscribed limits encoded in information systems.

This reasoning suggests that it is not IT per se that determines whether organizations will move toward centralization or decentralization. Rather, it is *managerial choice* about how to use IT that appears to make the difference (George and King, 1991; Robey, 1981). This observation has been formulated theoretically in terms of statistical moderation (Markus and Robey, 1988; Robey, 1981). In other words, whether executives choose to run an organization in a centralized or decentralized fashion is likely to influence whether the use of IT subsequently leads to centralization or decentralization. But here again, theory and empirical results suggest the possibility of "dual outcomes."

For example, one highly regarded stream of research suggests that IT reinforces the existing regime of power and control in organizations (Kraemer and Dutton, 1979; Pinsonneault and Kraemer, 1997). According to this theory, managers in organizations that are highly centralized to begin with are likely to use IT in ways that will increase central control, whereas decentralized organizations will become more decentralized as a result of using IT. This "reinforcement politics" perspective has received empirical support (Pinsonneault and Kraemer, 1997), especially in the context of the organizational size question, examined later.

On the other hand, some theorists have extended the earlier theory and interpreted empirical evidence to the opposite effect. For instance, in an award-winning paper, Huber (1990) theorized that, because the effects of computerization depend on the choices of decision makers at various organizational levels, the most likely outcome is a more uniform distribution of decision-making authority within and across organizations. In general, Huber predicted that IT would lead to more *de*centralized decision making in *centralized* organizations and more *centralized* decision making in *de*centralized organizations.

For Huber (1990), the prevailing distribution of authority in an organization was the most important contingency in the IT-leads-to-structural-change equation. However, the previously cited study by Blau et al. (1976) suggested that "the influences of automation may be more complex" (p. 37) than Huber proposed. Blau and colleagues compared manufacturing plants that had their own computers on-site and those that used off-site computer systems (probably in that era run by parent company headquarters), and found that the former had greater decision autonomy (were less centralized) than

the latter. "[T]he data imply that the location of computer facilities governs the locus of decision-making authority [of manufacturing plants]. If a plant has its own computer, its management is likely to have much autonomy, but if a plant uses an off-site computer, presumably in most cases at corporate headquarters, chances are the authority is centralized there" (p. 37). In other words, the most important contingency related to IT's effects on organizational structure may be managerial choice about *how to manage IT*, not overall organizational structure/decision-making authority as Huber (1990). (Of course, these two aspects of organizational design may be closely related.) The implications of this possibility are discussed in a later section of this chapter.

Further complicating the picture about the type, nature, and direction of IT's effects is the fact that the power of IT has increased substantially over time, allowing organizations to apply IT to a greater number of decisions and to decisions of ever greater complexity and strategic relevance. For example, organizations began using IT to make decisions about automobile and credit card loans in the early 1980s, but until the second half of the 1990s almost all U.S. residential mortgage loans were decided by human underwriters using judgment and rules of thumb. By 2000, however, nearly 100% of all mortgage lending decisions were made by automated underwriting systems (Markus et al., 2008). Changes in the application of IT over time means that the *ability* of senior organizational executives in large organizations to make more decisions (or to delegate more decision making to subordinates while retaining tight control over the decisions made) has increased substantially in more than 50 years since Leavitt and Whisler first made their predictions. This condition naturally raises questions about the consequences of IT for the employment of middle managers, discussed next.

In short, both theoretical arguments and empirical evidence suggest that the use of IT in organizations has dual outcomes regarding the centralization of decision making.

67.2.2.2 IT and Organizational Size

As discussed earlier, the size of organizations is believed to be strongly related to organizational structure. Larger organizations are generally more decentralized than smaller organizations and more formalized or bureaucratic. This relationship led some scholars to speculate that increased use of IT would lead to smaller firms. Two primary reasons were offered. First, IT can be used to automate some activities performed by middle managers. This labor substitution effect is expected to result in middle management downsizing (Brynjolfsson et al., 1994; Leavitt and Whisler, 1958; Pinsonneault and Kraemer, 1997). Second, following the theory of Oliver Williamson (Williamson, 1985), IT is seen as reducing costs that might make it profitable for an organization to outsource an activity to another organization (Afuah, 2003; Brynjolfsson et al., 1994). In this "make versus buy" decision, three kinds of costs are relevant: the cost of performing the activity, the cost of internal coordination, and the cost of external coordination. How IT changes the relative magnitudes of these costs is theoretically expected to shift the balance toward or away from outsourcing. If the organization outsources, it will be able to eliminate the jobs previously devoted to performing the activity and thus will get smaller.

In this area of research, as with research on centralization of decision making, results are mixed. Brynjolfsson et al. (1994) started with evidence that the number of employees in business establishments had decreased substantially in the prior 15 years, whereas the extent to which IT was used in business had increased enormously. Through analysis of a large dataset of U.S. businesses, they concluded that use of IT was associated with a decline in firm size. Although they took pains not to overgeneralize their findings, the authors concluded that IT was contributing to a restructuring of the U.S. economy.

Others, however, took issue with both the premises and the conclusions of Brynjolfsson and colleagues' research. Pryor (2001), for instance, argued that firm size is increasing, not decreasing, despite the waves of downsizing and outsourcing that occurred in the 1990s. Starting with arguments similar to those of Brynjolfsson and colleagues, Afuah (2003) concluded on theoretical grounds that the effects of Internet technology on firm boundaries (organizational size) should be moderated by

the nature of organizational technology (such as the interdependence among activities) and by the characteristics of information used. Therefore, in some industries, IT is likely to lead to *increased* organizational size.

Pinsonneault and Kraemer (1997) similarly found theoretical support both for the prediction that organizational size would decrease because of IT and for the prediction that IT would lead to larger organizational size. Therefore, they designed an empirical study to explore factors likely to moderate the relationship between IT and organizational size. They concluded that use of IT led to an increase in the number of middle managers in companies where decision authority (both for organizational and for computer-related decisions) was decentralized and a decrease in the number of middle managers where decision authority was centralized. This finding echoes that of Blau et al. (1976) about the association of computer location with plant managers' decision autonomy—computer location being a key IT-related decision. Pinsonneault and Kraemer further found that use of different types of IT resulted in different outcomes. Organizations that used IT more for coordination purposes had fewer middle managers, whereas those that used IT more for control had more middle managers. Finally, in a configurational argument, they reported that the impacts of IT on organizational size depended not just on individual structural arrangements but also on the congruence among structural arrangements, that is, the compatibility between overall patterns of organizational decision making and the distribution of IT-related decision making.

In short, both theoretical arguments and empirical evidence suggest that the use of IT in organizations has dual outcomes regarding organizational size.

67.2.2.3 IT and New Organizational Forms

A large and still active body of literature has developed around the hypothesis that the use of IT promotes the emergence of new organizational forms. This hypothesis is analogous to Chandler's observation that the railroads and telegraph enabled organizations to grow large, to diversify, and to innovate with the multidimensional form (see also Beniger, 1986; Yates, 1989). Some of the arguments and evidence in this literature overlap with research previously discussed, but generally scholars working in the new organizational forms tradition take a more holistic view of organizational design, focusing on configurations of attributes rather than isolated structural characteristics. However, scholars differ in their explicit or implicit characterizations of new organizational forms, and it is not always clear whether authors are discussing the same thing.

For example, Lambert and Peppard (1993) identified six different organizational arrangements as instances of new organizational forms associated with the use of information technology: (1) "network organizations": collections of legally independent organizations that partner by means of strategic alliances or outsourcing relationships to coproduce products and services that used to be produced by an integrated firm; (2) temporary task-focused teams within individual organizations, in which members may be widely dispersed geographically; (3) relatively stable networked groups inside organizations that do not have a particular task focus; (4) horizontal organizations, understood as involving the creation of customer- and/or supplier-facing coordinating units; (5) learning organizations, in which knowledge-management processes and tools may play a prominent role; and (6) matrix management, in which some organizational members report simultaneously to more than one superior. Lucas and Baroudi (1994) discussed four, somewhat different, "prototypical organizational designs or strategies that have emerged within certain industries or companies during the past two decades" (p. 10). These designs were labeled: (1) "virtual organizations" in which organizational members work together through IT with few constraints of time or space; (2) "negotiated organizations" in which a formerly integrated supply chain is crafted from contractual relationships among independent companies; (3) "traditional companies" in which IT may be used to reduce layers of management and/or restructure business processes; and (4) "vertically integrated conglomerates" in which IT is

used as an essential tool for coordination and task forces. (This latter type may be equivalent to the "multidimensional organizational form.")

More recently, Palmer et al. (2007) found five differences in language use and assumptions in the literature about new organizational forms: (1) whether the new forms involve revolutionary or evolutionary change; (2) whether the new forms are structurally simpler (smaller, less differentiated, less bureaucratic) or more complex (as for instance the "multidimensional" form is said to be); (3) whether the drivers of change are believed to be managerial choice or environmental influences (such as the widespread availability of low-cost IT); (4) whether the appropriate level of analysis is intraorganizational or interorganizational; and (5) and whether the "newness" of the organizational form refers to "new in time" or "new in a particular context" such as an industry or even a specific organization.

Palmer and colleagues' point (2) hints at the possibility of "dual effects" from use of IT. Their point (5) encompasses the observation that some of Lambert and Peppard's and Lucas and Baroudi's new organizational forms are arrangements *inside* organizations, whereas others refer to arrangements *between or among* organizations. These differences make it challenging to integrate the theories and findings of the new organizational forms literature; the following review is more illustrative than comprehensive.

Some studies focus on IT's effects on new *intra*organizational arrangements, such as the reduction of layers of hierarchy and the use of more lateral coordination mechanisms. These arrangements have labels like "virtual teams," "distributed organizing," or "internal markets" (DeSanctis and Monge, 1998; Halal, 1994; Orlikowski, 2002). For example, Hitt and Brynjolfsson (1997) theorized that organizations making heavy use of information technology would adopt a package of complementary organizational design arrangements including decentralization of decision making, subjective incentives, and greater reliance on skills and human capital. They found support for this hypothesis in the study of the detailed work practices and IT expenditures in large organizations. Orlikowski (2002) showed how the use of IT augmented direct interpersonal forms of coordination in a distributed new product development team in a global high-tech organization. Sambharya et al. (2005) concluded that the internal structures of multinational enterprises were becoming more "organic" in nature.

However, other studies suggest that the use of IT, particularly in global enterprises, has spurred the evolution of new *bureaucratic* organizational arrangements, characterized by much less decision autonomy for business unit heads and by much more impersonal coordination along with interpersonal coordination across business units. In a study of Irish subsidiaries of global multinationals, Finnegan and Longaith (2002) found large reductions in the autonomy of subsidiaries linked to the ways in which parent company headquarters used IT:

> For many subsidiaries studied, pricing and production decisions used to be within their range of activities as long as they stayed within corporate policies. This approach facilitated a level of local responsiveness. However, six subsidiaries now used enterprise resource planning (ERP) systems located at headquarters. This had resulted in the elimination of subsidiary management's input to pricing decisions. Corporate management also used the ERP system for drawing up a rolling overall production plan for the subsidiary …. IT was also found to play a similar role in selecting suppliers, engaging in research and development and devising the group's strategy. … IT therefore facilitates the ability of corporate management for excluding subsidiary managers from these types of decisions (p. 156).

Finnegan and Longaigh (2002) also found significant changes in the nature of cross-subsidiary coordination and again argued that the use of IT was responsible for these changes. In the traditional form of coordination, people in different units work directly together and make joint decisions through personal interaction. Finnegan and Longaigh found that the use of e-mail and groupware made

traditional coordination more personal than in the past, as Orlikowski (2002) also did. However, they also identified a new form of impersonal coordination that they called "programmed coordination," which they argued to be impossible without the use of IT:

> [Programmed coordination] is coordination without direct communication and it leads to the synchronization of activities as opposed to joint decision making. It is apparent more at an operational rather than a strategic level and, based on the findings of this study, it would be impossible to operate … without the aid of IT. An example … was where subsidiaries were obliged to consult a real time database in order to ensure that subsidiaries were not quoting for the same business (Finnegan and Longaigh, 2002, p. 157).

Finnegan and Longaigh's (2002) study provides a graphic illustration of the operation of management systems in what some experts claim to be a new organizational form, often called the multidimensional enterprise (Ackoff, 1999; Galbraith, 2000, 2008; Goold and Campbell, 2002; Palmisano, 2006; Strikwerda and Stoelhorst, 2009). Many environmental contingencies and strategic considerations have converged to promote the emergence of this form, and some observers suggest that IT is largely irrelevant. Galbraith (2000), for instance, claimed that the information processing demands of multidimensional organizations can be handled with relatively simple information technologies like spreadsheets. Others, however, insisted that integrated systems and corporate databases (e.g., ownership of subsidiary's customer and transaction data by corporate headquarters and a shared general ledger system in use across the firm) are required (Strikwerda and Stoelhorst, 2009), and Finnegan and Longaigh's study provides supporting evidence.

Many writers identify new organizational forms more with *inter*organizational than with the *intra*organizational arrangements just discussed. Here many observers agree that the use of information technology has made it easier for people to coordinate activities across organizational lines and has therefore been a factor in the increased incidence of outsourcing, joint ventures, and other kinds of cooperative interfirm arrangements (Fulk and DeSanctis, 1995; Lucas, 1995; Malone et al., 1987; Zammuto et al., 2007), including the development of interorganizational coordination hubs, in particular business sectors (Markus and Bui, 2012).

Ahuja and Carley (1998), Majchrzak et al. (2000), and Argyres (1999) provide particularly rich case examples of the use of IT to facilitate these new (or at least more widespread) forms of interorganizational networking. For example, the B-2 "Stealth" bomber was an aircraft designed by four independent firms almost entirely by computer. In analyzing this case, Argyres (1999) found that the use of information systems: (1) made coordination across the firms less costly; (2) made the governance of the project more efficient by establishing social conventions that rendered resort to hierarchical authority less necessary; (3) reduced risks that result from poor distribution of information across firms; and (4) decentralized decision making. A comparative study (using data aggregated at the industry level) found evidence that multinational enterprises in information-intensive industries that use IT heavily are more likely to contract with other organizations to perform activities that were traditionally performed internally (Rangan and Sengul, 2009).

The general consensus in the new interorganizational forms literature is that IT promotes horizontal, decentralized, or networked organizational forms. But even here, the possibility of dual effects has been raised. Sahayam et al. (2007) theorized that, because IT can enhance coordination both within and between organizations, IT can promote both tightly coupled organizations (such as vertically integrated companies or ones with strong central control) as well as loosely coupled organizations (such as organizations that rely on alliances with other organizations or those that engage workers on contract instead of through employment). In an industry-level study, they found that the relationship between the use of IT and loosely coupled forms of organization was more frequent in industries with industry-wide product or process standards and low technological change.

By extension, Sahaym and colleagues' findings suggest that other organizations may be using IT to support *more tightly coupled* interorganizational coordination. Steinfield et al. (2012) reviewed the arguments and evidence in support of this proposition. Through a case study of an international coordination

hub serving the automotive industry, Steinfield et al. illustrated how the use of IT can promote tighter interorganizational coupling.

In short, the literature on IT and new organizational forms also provides some evidence of dual outcomes.

67.2.2.4 Summary

For a half century, scholars of varied theoretical orientations have explored the relationship between IT and organizational structure. The three related issues of centralization or decentralization of decision making, organizational size, and new organizational forms have been the primary foci of research. Trying to make sense of the literature is hampered by differences in theory, concepts, and context, not to mention the fact that the capabilities and applications of IT have grown enormously over the time period.

Nevertheless, regardless of research focus and research time frame, one remarkable consistency runs through the literature. Both theory and empirical evidence strongly suggest that the relationship of IT with organizational structure is one of "dual outcomes," as Pool observed long ago in the context of telephone technology (1978). Robey's conclusion of 30 years ago, "several different organizational structures [are] compatible with computer information systems" (1981, p. 686), seems equally valid today.

This conclusion may be discouraging to some readers, but it should have the opposite effect. When one digs deeper into the findings, one can see that they offer practically important recommendations to practitioners, and they suggest exciting theoretical and methodological challenges for future scholarship.

67.3 Impact on Practice

The research on IT and organizational structure has two major implications for practitioners. First, the literature tells us a great deal about how IT can *constrain* organizations' ability to adopt new organizational designs successfully; conversely, adopting new designs often requires major changes in systems support. Put differently, good organizational design involves making careful decisions about the nature of IT infrastructures and platforms, which is a critical insight of the "enterprise architecture" discipline. Second, the literature tells us that *organizational designs for IT management* are also critical for good organizational performance. IT management design does not have a necessary one-to-one relationship with overall organizational design. However, certain ways of organizing IT management are not capable of producing the systems needed by some organizational designs. Therefore, practitioners should pay close attention to the implications of the literature both for system design or selection and for organizing and managing IT services.

67.3.1 Fit between Organizational Structure and Information Systems

The literature on IT and organizational structure does not support the idea that using IT changes organizational structure in any one particular way (e.g., toward centralization versus toward decentralization). The literature does not even support the idea that using IT changes organizational structure in different ways under different conditions. (Recall that it is not *IT* per se that changes organizational structures; *managerial decisions* about whether, when, how, and why to use IT and *managerial actions* are certainly the most critical factors.)

But the literature does suggest practical implications. First, an organization's legacy of IT may make it difficult, if not impossible, for an organization to adopt new organizational structures or designs. Some years ago, I studied organizations that had redesigned their business processes (Bashein et al., 1997). As a result of process reengineering, an insurance company decided to change its processes for handling claims. The company had been functionally organized; the new design was organized by market segment. That is, the company decentralized into customer-oriented groups, each of which would be free to adopt different policies for claims processing. Fortunately, the company's claims processing system was flexible enough to adapt to this change, but the company's management information systems were not. The information systems produced reports that were useful for functional unit heads, but they did

not provide information broken down by customer segment. Every single management report had to be reprogrammed, before the organization was able to move to the new organizational design.

Another example of how IT can hinder organizations' ability to function effectively given their organizational designs is Microsoft, which adopted SAP's financial systems in the mid-1990s (Bashein et al., 1997). Microsoft has a multidimensional organizational design (Strikwerda and Stoelhorst, 2009), meaning that it manages products, markets, and projects—three organizational dimensions that overlap in multiple ways. At the time Microsoft implemented SAP financials, the software product did not provide good support for a three-dimensional company like Microsoft, because it allowed companies to "tag" transactions in only two ways (e.g., by product and market, but not also by project) (Bashein et al., 1997). Unwilling to modify SAP software, Microsoft circumvented the software limitation, painfully, by making people work with a complicated chart of accounts. This constraint was so vexing that Microsoft upgraded to a new version of SAP, which did support three organizational dimensions, as soon as it was available.

A corollary of the first point is that successfully moving to new organizational designs often requires major information systems modifications or entirely new system implementations. The process can be seen in detailed case descriptions of companies like Procter and Gamble (P&G) (Galbraith, 2009; Piskorski and Spandini, 2007) and Nestlé (Steinert-Threlkeld, 2006). In the late 1990s, both of these large multinational companies were structured in a fairly decentralized manner: Managers in different geographic regions had considerable decision-making autonomy. This was believed necessary because preferences for consumer products vary greatly around the globe. But many support functions such as accounting, human resources management, and IT were also decentralized, which encouraged variations in business practices and increased costs.

Several factors motivated a change in organizational design, including recession, declining organizational performance, and perceived needs to standardize global brand images and to be more responsive to the needs of multinational retailers. Consequently, both organizations among many others adopted new organizational designs characterized by much greater centralization and standardization in certain areas.

P&G, for instance, created a new Global Business Services (GBS) unit, with facilities in three geographic locations (San Jose, Costa Rica, and Newcastle) (Delong et al., 2005; Sia et al., 2010). The mission was to provide a wide array of standardized support services to all of P&G's facilities in each region. (Previously, each facility had performed those activities for themselves, and there was less standardization across locations.) The support services provided by GBS included a number of core business activities, such as market research and merchandising, in addition to traditional "support" activities, such as human resources management and IT.

P&G's legacy information systems were not up to the task of supporting this new organizational design, and P&G embarked on a multiyear systems initiative to implement the SAP-integrated enterprise information system. It is clear that IT did not cause this organizational change: The intent to reorganize preceded the system project. However, the new organizational design could not have worked without change in the company's legacy information technology. (Imagine a geographically and organizationally centralized "shared services center" trying to provide standardized services while using a patchwork of nonstandardized information systems running in many dispersed organizational locations. Impossible!)

A third practical implication of the literature on IT organizational structure is that once systems are in place to support a new organizational design, people will discover new ways to use the systems, and the organizational design will evolve. But the organizational design will only evolve up to the point where it is again constrained, this time by the new systems.

In short, the literature on IT and organizational structure offers practical advice that can be summarized as the "Principle of Enterprise Architecture": Design an organization's IT infrastructures and digital platforms to support the organization's "TO BE" (versus "AS IS") organization design. If you design organizational IT to support the existing organizational design, IT may prevent movement toward a preferred organizational design.

A concrete statement of this principle can be found in Ross, Weill, and Robertson (2006). According to Ross and colleagues, organizations with multiple business units can have different "operating models"

(organizational design configurations). The "Unification" model is the classic U-form organization like an airline—a single business company with globally standardized business processes. If Unification is the preferred ("TO BE") operating model, Ross and colleagues prescribe enterprise systems that support globally standardized processes and global access to data. The "Replication" operating model is one with multiple, nearly identical, business units: A hotel chain is a good example. For this type of enterprise, a standard IT infrastructure and set of applications is needed that can then be "replicated" in locations around the world. The "Coordination" operating model describes a multi-business company in which the partially independent business units need to coordinate frequently, for example, an insurance company with multiple product lines serving the same customers. Here, the IT platform needs at minimum to be able to provide access to shared data through standard technology interfaces. Organizations with the "Diversification" operating model have independent business units with different technologies and customers (e.g., the Sears holding company, which includes financial services as well as retailing). Here, the need for sharing information across units is low, but IT can provide economies of scale through a light "shared services" platform that does not restrict business units' strategic flexibility.

In short, the literature on organizational design and structure has much to offer practitioners in the way of advice about appropriate systems and technologies.

67.3.2 Managing Information Systems

A second practical implication of the literature on IT and organizational structure concerns, not just the systems and technologies organizations use, but also *how they choose to manage IT* (Earl, 1996; Galliers and Currie, 2011; King, 1983). Managing IT involves many decisions such as (1) whether to provide IT services internally or to contract with external service providers (like IBM or Accenture) for those services; (2) how to organize (structure) people in the organization who perform or manage IT services; (3) *how to make decisions about* which information technologies, systems, and services to adopt, and so forth. In other words, organizations have *designs for IT management* in addition to their overall organizational designs.

Therefore, an important practical question for every organization is: "What should be our organizational design for managing IT?" As you might expect, there is likely to be some relationship between overall organizational design and IT organizational design. For example, if an organization is highly decentralized, perhaps because it has a strategy of unrelated diversification (e.g., the "Diversified" operating model), chances are good that the organization would not only have different IT and systems in different units but would also decentralize the management of IT and systems to the diversified business units. Conversely, if an organization is centralized (e.g., the "Unified" operating model) at the enterprise level, it seems likely that the organization would also choose to have centralized IT management.

And, in fact, a fair number of studies have addressed the relationship between organizational design at the enterprise level and IT management design, particularly in global companies (Alavi and Young, 1992; Jarvenpaa and Ives, 1993; Karimi and Konsynski, 1991; King and Sethi, 2001; Ramarapu and Lado, 1995). This research generally reports a correspondence between organizational strategy and structure, IT management design, and the types of information technologies and systems used.

But the correspondence between organizational design and IT management design is not as close as you might think, because additional considerations enter in. One consideration is history. Computers have not always been as powerful as they are today, and their smaller capacity in the past encouraged decentralized IT management. For example, Southwest Airlines, a "Unified" organization, used to allow each functional unit head to manage its own IT unit and develop its own systems, partly for historical reasons. Today, Southwest has a centralized IT management design (Ross and Beath, 2007), in part because of concerns about IT management costs arising from duplication of effort, lack of standardization, etc., and in part because that way of organizing IT is more "congruent" (Pinsonneault and Kraemer, 1997) with Southwest's overall organizational design. A second reason for the correspondence between organization design and IT management design being less than complete concerns the flexibility of today's centralized IT management design. Organizations can set up centralized IT services and

operate them in a way that will produce either (1) standardized and integrated IT, systems, and services for use across an organization or (2) IT, systems, and services that are tailored to the needs of individual business units.

Although a centralized IT organizational design can support either a centralized or decentralized organizational operating model, the reverse is not true. If an organization has a very decentralized design for managing IT (i.e., each business unit makes its own decisions about IT), there is almost no way this IT management design would be able to produce IT systems and services that are integrated, standardized, or commonly used *across the entire organization*. The practical principle here is: IT management design for an organization should be *no less centralized* than the overall organizational design or operating model.

67.3.3 Summary

Findings of the literature on IT and organizational structure do not guarantee practitioners particular organizational outcomes like greater top-down control or improved lateral coordination. But they nevertheless have important practical implications.

For example, Blau et al.'s (1976) finding that managers of plants with their own computers on-site had more decision autonomy than managers of plants with computers at parent company headquarters provides useful insights. This finding tells us that the parent companies of the plants with their own computers (1) had decentralized organizational designs for managing IT, (2) had technologies, systems, and services that were tailored to the needs and preferences of individual plant managers, and (3) therefore, parent company executives would have had great difficulty in exerting stronger top-down control without changing the systems used by plant managers, (4) which in turn would have also required them to change the IT management design in the direction of greater centralization.

As another example, Pinsonneault and Kraemer's (1997) finding that use of IT led to an increase in the number of middle managers in organizations that were decentralized both at the enterprise level and in their IT management also provides practical insights. Business units in these organizations had to add middle managers *to manage IT*. The technologies, systems, and services they produced were not shared with other business units, compounding the increase in middle management staff. A different organizational design for IT management in the same decentralized companies would have led to a much lower increase in middle management staff. In short, research on IT and organizational structure has much to offer to IS and IT practitioners in the way of advice about how to organize and manage IT.

67.4 Research Issues

The consistently mixed findings in research on IT and organizational structure certainly call for more research and theorizing, but not necessarily more of the same. The research record suggests the need for new theoretical perspectives and raises some promising questions for future research.

67.4.1 Need for New Theoretical Perspectives

Organizational structure is a foundational concept in a number of disciplines, including strategic management, organizational theory and economics, and information systems. However, possibly because research results about the role of IT in organizational structure change seem so mixed, scholarly attention has drifted toward other issues, particularly toward IT governance and toward informal, lateral relationships within and across organizations (Brown and Grant, 2005; Martinez and Jarillo, 1989; Whittington and Mayer, 2001). This move is a step backward from the work of scholars like Blau, who explicitly recognized the interplay between organizations' structural characteristics and informal interactions, or Chandler, whose broad conception of organizational structure included both formal/vertical and informal/lateral dimensions.

Without looking at both structure and informal relations, scholars are not able to address how these two dimensions of organizations are (or are not) *aligned* and how they *interact* in different organizational design configurations. The alignment or nonalignment among various dimensions of organizations is a central theme in many literatures. For example, in the IS literature, scholars have proposed the theory of strategic alignment (Bergeron et al., 2004; Chan and Reich, 2007b; Henderson and Venkatraman, 1993) to explain variations in organizational performance. The core hypothesis of this literature, supported by systematic research as well as casual observation, is that organizational elements (e.g., IS strategy and business strategy, organizational structure and systems, or IT policies and IT practices) are not always aligned, and that lack of alignment contributes to intraorganizational conflict and ineffectiveness (Bergeron et al., 2004; Chan and Reich, 2007a).

Despite the centrality of alignment theory, the types, sources, and consequences of alignment and misalignment among aspects of organizational design, including IT and IT management arrangements, have not been fully explored. There are many possible "alignment" relationships among organizational elements: One element may dominate another (Sambamurthy and Zmud, 2000). One element may reinforce another (Argyres and Silverman, 2004). One element may suppress or dampen the effects of another (Markus et al., 2013). Understanding these possibilities is necessary, if research on IT and organizational structure will be able to produce reliable recommendations for practice.

Further, as noted both by IT alignment scholars such as Chan and Reich (2007b) and by organization structure scholars such as Whittington (2002), we need better theories about the dynamics of structural change and alignment. Whittington (2002), for example, recommended further development of the practice perspective on organizational structure. Such a theoretical perspective would be particularly valuable for the study of IT and organizational structure, because it would emphasize "the role of particular functional areas or skills [such as accounting or IT] to the working of structure" (Whittington, 2002, p. 130).

Another promising theoretical perspective for the study of IT and organizational structure is evolutionary (or coevolutionary) theory (Dosi and Marengo, 2007; Lewin and Volberda, 2011; Romanelli, 1991; Williams, 2008), which has also seen some application in the IS literature (Lewis, 2008; Peppard and Breu, 2003). Evolutionary theories posit reciprocal causal relations between concepts such as management intentions and aspects of organizations and their environments such as organizational structures and information technologies. A particularly valuable application of evolutionary theory would be to examine the role of IT in the diffusion of new organizational forms.

For example, I earlier described the difficulties Microsoft encountered in the mid-1990s when it tried to adapt SAP software (an enterprise software package widely used by large organizations) to its multidimensional structure. A few years later, the SAP package did support multidimensionality, and, around that same time, a number of other large companies (e.g., Nestlé and P&G) both restructured and implemented the SAP package enterprise-wide. Twenty years earlier, Golden Triangle Corporation had painfully modified an accounting package to make use of modern database management technology in order to realize its organizational design intentions (Markus, 1983, 2010). Later, accounting packages employing database management technology became widely available commercially. This is precisely the era when the multidivisional organizational form (pioneered in the 1920s) diffused rapidly (Fligstein, 1985).

I believe there is a story here. It is not a story of simple causality (IT causes change in organizational structure), but rather one of reciprocal causation (Wagner et al., 2005) in which organizational needs for new ways of organizing intersected with the software development trajectory, fueling further evolution of both.

In short, much remains to be learned about the role of IT in organizational structure change. New and better theories are one way to get there. In addition, the survey of literature in this chapter suggests a few specific research issues for scholars in the information management tradition.

67.4.2 Unanswered Research Questions

It is now well established that *IT* contributes to organizational effectiveness under certain circumstances (Melville et al., 2004). And scholars have examined how patterns of alignment among multiple organizational design dimensions including *IT management* have contributed to organizational performance (Bergeron et al., 2004). However, there is little comparative research linking alternative IT management designs to organizational performance outcomes.

For example, I noted earlier that a centralized IT-shared services model could be used to provide standardized IT capabilities shared across an entire complex organization or to provide IT capabilities customized to individual business units. Both approaches are likely to be more cost effective than entirely decentralizing IT management to business units. The standardized approach is likely to be less costly than the customized one, but it may involve reduced effectiveness for business units. How much difference do these organizational models make for overall organizational performance? The literature does not, to my knowledge, clearly answer this question.

Second, we know relatively little about how and why *lack of* alignment between various aspects of organization design occurs and what difference it makes. For instance, the World Bank, a highly decentralized organization, adopted an IT-shared services model similar to that of P&G and other more centralized organizations (McFarlan and Delacey, 2003). Does this apparent lack of alignment represent an indicator of, or contributor to, poor organizational performance? Or could it mean that there really is "one best way" to organize IT today in large global organizations (Markus et al., 2012)? If that were the case, we should certainly find out why, because it shakes the foundations of the contingency theory of alignment.

All told, IS scholars have not yet exhausted the topic of IT and organizational structure. Among other possibilities, organizational structure provides a valuable lens for exploring the relationship between IT management and organizational performance.

67.5 Summary

The role of IT and organizational structure has been a topic of speculation, theorization, and empirical research for over 50 years. In particular, research has examined the effects of IT on organizational centralization, organizational size, and new organizational forms. In all three areas, scholars have produced theoretical arguments and empirical results consistent with the "dual effects" hypothesis—the idea that advances in information technology can result in opposite structural consequences simultaneously and coterminously.

Some scholars interpret evidence about dual effects to mean that IT is irrelevant to changes in organizational design. These scholars argue that only managerial intentions and actions ("human agency") are a factor in the outcomes. However, there is considerable evidence that IT does indeed make a difference, even if IT alone does not cause the outcomes observed.

This conclusion has important practical implications. Specifically, organizations are advised to align (or co-design) their information systems and technologies with their strategies and structures. In addition, organizational structure should be an important consideration among several in the design of effective IT management arrangements.

At the same time, much remains to be learned about the processes by which organizational structures intersect with technologies both within individual organizations and across organizations and over time. In addition, much more needs to be learned about organization designs for IT management and how they contribute to, or hinder, organizational effectiveness.

Acknowledgments

This research was supported in part by the National Science Foundation under award number SES-0964909. I wish to thank colleagues at Bentley University, Nanyang Business School (Singapore), and MIT's Center for Information Systems Research for their many contributions to this project.

Open Innovation: A New Paradigm in Innovation Management

Sirkka L. Jarvenpaa
University of Texas at Austin
Aalto University

68.1 Paradigm Shift in Innovation Management

Kuhn (1962, p. 103) writes, "[Paradigms] are the source of the methods, problem-field, and standards of solution accepted by any mature scientific community at any given time."

Organizational innovation management is experiencing a paradigm shift. In this chapter, the technological drivers for the open paradigm are discussed followed by key concepts of innovation management including innovation funnel, radical and incremental innovation, exploration and exploitation, and organizational change. We then contrast closed and open innovation and highlight some selected forms, approaches, and practices of open innovation. We review major and promising theoretical models and present questions for further research. Open source will be reviewed as part of open community models.

Innovation means creating and implementing new ideas, services, technologies, business models, applications, or processes (Gupta et al. 2007). Only when an idea or invention is successfully applied to practice does innovation take place (Schumpeter 1942). Innovation can take place in just about any

human activity. Innovation is particularly critical when an organization faces one or more of the following: technological discontinuities, global competition, new markets, new competitors, collapsing product and service life cycles, or new customer value systems.

Traditionally, a firm's research and development (R&D) and product development departments generated and managed innovations. Sometimes, this centralized approach would then delegate responsibility to business units organized by products and markets or both. Innovation in services was haphazard at best. Now, there is a greater recognition that innovation affects everything the organization or company does including but not limited to logistics and human resource management, marketing and customer management, production management, information systems, financing and capital management, and public relations. Nearly any job opening highlights innovation management as a core skill set. Never has innovation been as valuable as it is now.

Information and communication technology (ICT) plays a major role in the innovation revolution because it converges multiple technologies enabling access to vast amount of data. ICT complements business and work processes and innovative management techniques that make innovations possible. ICT has fundamentally transformed innovation from an internal activity into an open and network-based business process (Brynjolfsson and Saunders 2010). ICT makes it possible to innovate across geographic and organizational boundaries and reach out to millions of people for their ideas and their assessments. ICT has led to large-scale, fast-cycle experimentation. Real-time data capture, storage, mining, visualization, simulation, and rapid prototyping allow companies to dramatically reduce development cycles and test novel combinations faster than ever before (Dodgson et al. 2006).

Technological changes have opened the innovation activities from inside the firm toward external networks. Shell's GameChanger process brings together ideas from inside and outside the company, including academic researchers, to collaborate on new technologies and business ideas. A number of initiatives have emerged that use virtual worlds and digital games (Schultze et al. 2008). For example, the Institute for the Future uses massively multiparty online war game as a way to collectively address major problems together with the U.S. Office of Naval Research. Much innovation now takes place under an open paradigm: open innovation (Chesbrough 2003), open source (O'Mahony 2003), user innovation (von Hippel 2010), open communities (Faraj et al. 2011), social production (Benkler 2006), and sponsored co-creation (West and O'Mahony 2008). Large-scale unifying communications networks create a global community for producing, distributing, and consuming innovative ideas, products, and processes.

The open paradigm to innovation lowers the barriers to entry and enables small and large companies to participate in the innovation revolution. Global companies such as Procter & Gamble traditionally relied on their internal brick and mortar R&D functions to produce innovations. The company was very insular in terms of the ideas it developed and launched. However, by early 2000, the company adopted a new radical strategy of open innovation. Their "Connect and Develop" model focuses on identifying promising ideas anywhere in the world and bringing them to the company to enhance and capitalize on internal capabilities. The company also launched an Internet-based innovation intermediary (NineSigma). This new model of innovation allows the firm to innovate more with less and shorten its development cycles (Sakkab 2002). In some cases, R&D costs were cut 60% (Huston and Sakkab 2006).

Another company leveraging the paradigm shift in innovation is Threadless, a small Chicago-based company with less than 20 employees. Threadless operates t-shirt design competitions through its website. Globally, over one million people, many of whom were professional designers, submit designs (Howe 2006; Brabham 2010). The designs are then posted and voted on each week. Using all this information, the firm selects the final prints for the t-shirts that it produces.

Open innovation is best thought of as a paradigm shift in innovation management (Huizingh 2011). Openness has been long valued as bringing important diversity in the early phases of innovation, but more recently in other phases of the innovation as well (Granstrand et al. 1997). Openness takes varied forms in different phases (Dahlander and Gann 2010). Open innovation can involve integrating external ideas with internal organizational capabilities and resources, as well as effectively using intellectual property (IP) for appropriating value from innovations (Chesbrough 2003; Lichtenthaler 2011).

Open innovation can also mean exploiting open communities without legal constraints (von Hippel 2010). As problems grow more complex, Internet-based innovation communities make it possible for an almost infinite number of firms and individuals (who may not even know of each other's existence) to work independently yet contribute to the overall innovation (Faraj et al. 2011).

Open innovation in its varied forms and approaches has gained popularity globally and across industries. Early research and writing began in North America and Europe (e.g., Chesbrough and Teece 1996; Granstrand et al. 1997). There is a growing body of open innovation literature in Asia (Asakawa et al. 2010; Lee et al. 2010) and Latin America (Gomes and Kruglianskas 2009). Governmental bodies, eager to improve their economic competitiveness, are very interested in open innovation (de Jong et al. 2008; Almirall and Wareham 2011; Jarvenpaa and Wernick 2011). Leveraging innovation in open networks is not limited to high-technology sectors (e.g., Intel, Apple, and Google) but is increasingly exploited in mature industries and service businesses (Chesbrough 2010; Chiaroni et al. 2010) and in small- and medium-sized firms (van de Vrande et al. 2009). Open innovation is also leveraged in nonprofits (Holmes and Smart 2009; Lakhani et al. 2012). As research continues and is disseminated and as technology continues to converge, more individuals, companies, and governments embrace the open innovation paradigm and reap its benefits.

68.2 Key Concepts in Innovation Management

The field of innovation management is rich with many concepts, frameworks, and models. It bridges many disciplines including organization theory, economics, information systems, communications, sociology, psychology, geography, and history. Successfully connecting these various disciplines requires a holistic management approach. Interested readers are referred to many handbooks that take a holistic view on innovation (e.g., Nooteboom 2000; Burgelman et al. 2004; Fagerberg et al. 2005). With an understanding of the interconnectedness inherent in innovation management, we next review some key concepts that are particularly valuable in understanding open innovation.

68.2.1 Innovation Funnel

The "innovation funnel" (see Figure 68.1), also called stage-gate model, was developed in the 1980s as a way to understand how a firm decides which innovations to pursue and how to pursue them (Cooper 1988). Innovations go through four to five stages such as idea generation, concept development, testing, and commercialization. Each stage typically involves more resources than the previous one, resulting in increased commitments. At the beginning, in the idea generation stage, the firm engages in technology and market assessments that generate a sizable number of ideas and possible opportunities.

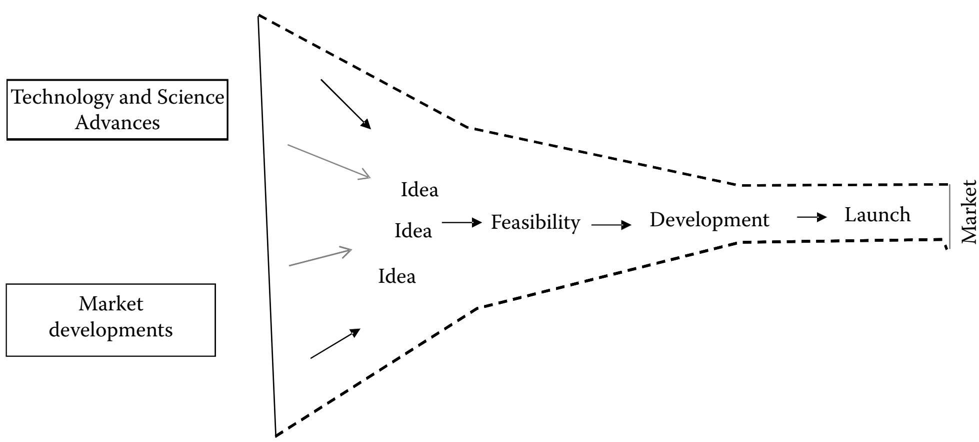

FIGURE 68.1 Closed innovation system.

These may include customer or market need, new product concept, scientific breakthrough, competitive advantage, and so on. At the first gate, the ideas and opportunities are evaluated, and a determination is made whether to proceed into the next stage. A broad set of factors may be considered including the current technology strategy, product/market strategy, competitor analysis, political risks, etc. If the idea passes the first gate then it progresses to the second gate: concept development, if successful there then to the third gate, testing, and if passes that gate on to commercialization (Gronlund et al. 2010).

Many have criticized the funnel as anti-innovative because it creates a linear and rigid process (Nichols 2007). If the innovation fails any of the gates, the innovation is put on the shelf. The gates can involve heavy evaluation processes to the point that more resources are allocated to evaluating and eliminating innovations rather than improving the innovations. The innovation funnel engenders "false negatives." These are ideas that are weeded out by internal groups and remain unused and underutilized by the firm. However, many such ideas might be valued by others outside the firm. The funnel only considers internal paths to market. The funnel does not encourage ideas from outside except in the first stage. There are often strong norms against innovations that are not internally developed, so-called not-invented-here syndrome. The funnel emphasizes alignment between the innovation and the firm's strategy (Gronlund et al. 2010).

68.2.2 Radical versus Incremental Innovation

Different types of innovations (product, process, business models, architectural), as well as innovation processes, are commonly discussed in terms of a continuum from incremental to radical. This continuum reflects the relative newness and uniqueness of the innovation from preexisting alternatives and knowledge bases (Dewar and Dutton 1986) and has a major impact on future developments (Dahlin and Behrens 2005). "An innovation is *radical* when innovators need to acquire extensively *unique* and *novel* technological and process-related *know-what*, *know-why*, and *know-how*" (Carlo et al. 2012). Radical innovations are considered as frame breaking and transformative yet highly risky and uncertain. Radical innovations or radical innovation processes are based on different and unconventional technologies or scientific principles, fundamentally change the cost/benefit ratios, require new cognitive frames, open new use contexts and applications, and lead to new markets (Henderson and Clark 1990).

By contrast, incremental innovation "introduces relatively minor changes to the existing product and exploits the potential of the established design" (Henderson and Clark 1990, p. 9). Incremental innovations are competence enhancing, whereas radical innovations are competence destroying (Henderson and Clark 1990). Radical innovations are new-to-the-world, whereas incremental innovations are new-to-the-firm (Henderson and Clark 1990).

Radical and incremental innovations have different economic and organizational consequences. It is well accepted in innovation management literature that firms that enter the market early and introduce offerings with a high level of originality derive more commercial value (Utterback 1994; Christensen 1997). This is the case not only in product-based industries but also in services (Love et al. 2011; Therrien et al. 2011). All this requires ever-greater diversity, mobility, and scale in innovation, as well as "creative destruction" (Schumpeter 1942) and "creative abrasion" (Leonard-Barton and Swap 1999).

Yet, pursuing radical innovation is not always a preferred strategy. At times, rushing to embrace the unique and novel can be detrimental to the firm's viability (Charitou and Markides 2003). Radical innovations can pose high knowledge requirements for their adopting units (Carlo et al. 2012). Radical innovation is much more difficult and risky to implement (Damanpour 1988). A multitude of factors must be considered and each individual situation must be thoroughly assessed to determine the feasibility of pursuing either radical or incremental innovations.

68.2.3 Exploration and Exploitation

Exploration and exploitation represent two other core concepts in innovation management. Exploration involves the generation of an idea or invention; exploitation involves the conversion of the idea or

invention into a solution, business, or application that can be used to generate a profit. All innovative activity involves exploration and exploitation as their main activities (March 1991). Exploration involves "search, variation, risk taking, experimentation, play, flexibility, discovery, and innovation" (March 1991, p. 71). Exploration is about value creation: new learning and knowledge, tasks, functions, and activities that maximize opportunities. Exploration is associated with uncertainty over value appropriation as the future markets, customers, application areas are still unknown. Traditionally, to manage this uncertainty, firms limit their exploration activities to a limited number of parties to maintain control yet leverage informal relationships for the transfer of tacit knowledge.

Exploitation refers to "refinement, choice, production, efficiency, selection, implementation, and execution" (March 1991, p. 71). Exploitation is about efficient use of existing knowledge and assets, routines, standard operating procedures, and formal relationships. Exploitation is about maximizing income from innovation or gaining the maximal utility or use value from innovation. In exploitation, markets are known and focus is on maximizing transaction efficiency.

The organization's ability to achieve a balance between exploration and exploitation is referred to as organizational ambidexterity (Tushman and O'Reilly 1996; Gibson and Birkinshaw 2004). Organizational ambidexterity is challenging as the requirements for leadership, structures, and processes regarding exploration and exploitation are very different even paradoxical (Dougherty 2006; Lavie et al. 2010). Yet, successful innovation requires management of exploration and exploitation at a high level in a complementary fashion (Katila and Ahuja 2002). Organizational ambidexterity requires a holistic view of innovation (e.g., Linder et al. 2003). The innovation value chain (Hansen and Birkinshaw 2007) provides such a view through (1) idea generation, (2) conversion, and (3) diffusion. The innovation value chain interlinks knowledge generation and sourcing by transforming this knowledge into new services and commercialization of these new services to grow business.

68.2.4 Organizational Change

The more radical the innovation, the more challenging the organizational change. Radical innovation means undergoing discontinuous change processes including a cultural change not just in the firm but often also in the broader networks of customers and suppliers. In the vocabulary of radical change theorists, discontinuous change requires *deep structural changes* where basic values, business practices, culture, and organizations change (Tushman et al. 1986). Without a deep structural change, behaviors migrate back toward the old ways of operating, reinforced by the existing processes, structures, incentives, and cognitive frames (see Figure 68.2). The weakest link in the network can undermine accomplishments elsewhere. Some level of identity crisis, disorder, and ambiguity usually precedes a deep structural change that sticks. Therefore, a long-time horizon and high level of organizational, architectural, managerial, and legal competencies are required for successfully implementing a radical innovation. Done in this manner, new incentives and mind frames are adopted and accepted and successfully replace the old behaviors.

For example, Procter & Gamble found that it took 5 years of investments, sourcing ideas externally, and developing online knowledge exchange sites before the firm began to see returns from the transformation of its innovation process from an internal model to an open innovation model (Hansen and Birkinshaw 2007). The transition from closed to open innovation meant radical change for Procter & Gamble. Open innovation required many technological and organizational investments such as partner networks, open innovation business units, platforms to transfer knowledge externally and internally, and IP protection systems (Gassman and Enkel 2004; Huston and Sakkab 2006; Chiaroni et al. 2010; du Chatenier et al. 2010). Procter & Gamble's long-time horizon and high-level organizational, technological, managerial, and legal competencies enabled a successful radical change to open innovation.

Without the correct structures in place, failures are common. A global firm with a large customer base was unable to transfer and leverage even a single external unsolicited R&D even though "it participated in many forms of external innovation such as open source software development, patent donations, and open

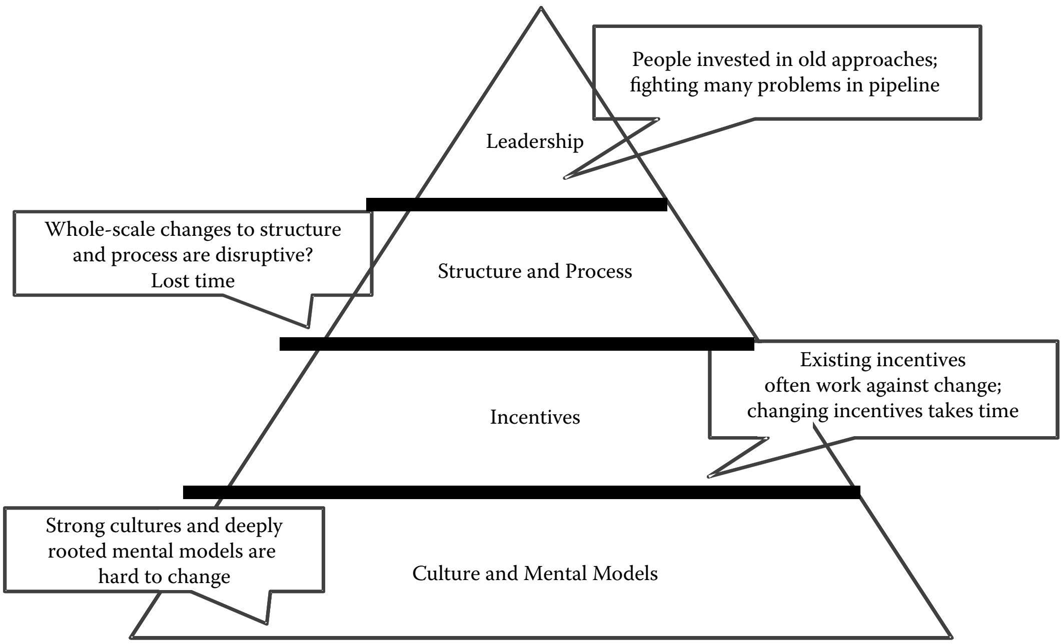

FIGURE 68.2 Organizational challenges to innovation. (Adapted from Cummings, J. Personal Communications, 2011.)

research calls" and was proud of its capabilities at engaging in open innovation (Alexy et al. 2012, p. 122). Such failures abound although they are not currently well captured in the literature.

68.3 Open Innovation

In the 1990s, increased investments in R&D in the automotive, energy, pharmaceutical, and other industries produced declining rates of innovation (e.g., Barrell et al. 2000). Open innovation addressed this issue and became a way to boost a firm's innovative capacity, grow, and increase market share (van de Vrande et al. 2009; Drechsler and Natter 2012). Open innovation augments internal capabilities with complementary capabilities, network externalities, and access to new relationships (Chesbrough and Crowther 2006). If implemented correctly, open innovation can enable growth and increase market share.

68.3.1 Henry Chesbrough on Open Innovation

In the book entitled, *Open Innovation: The New Imperative for Creating and Profiting from Technology*, Henry Chesbrough (2003) popularized the notion of "open innovation." This book has proven to be highly influential. It had more than 5740 citations as of August 2012. There were 1800 citations in July 2010 (Huizingh 2011), just 7 years after the book was published. Chesbrough (2012, p. 20) wrote

> When I wrote *Open Innovation* in 2003, I did a Google search on the term "open innovation," and I got about 200 links that said "company X opened its innovation office at location Y." The two words together really had no meaning. When I conducted a search on that same term last week, I found 483 million links, most of which were about this new model of innovation.

Chesbrough (2003) contrasted open innovation to "closed innovation." Closed innovation refers to a vertically integrated innovation model. The company largely relies on its own innovation investments, processes, and structures for exploration and exploitation (March 1991). In terms of the innovation

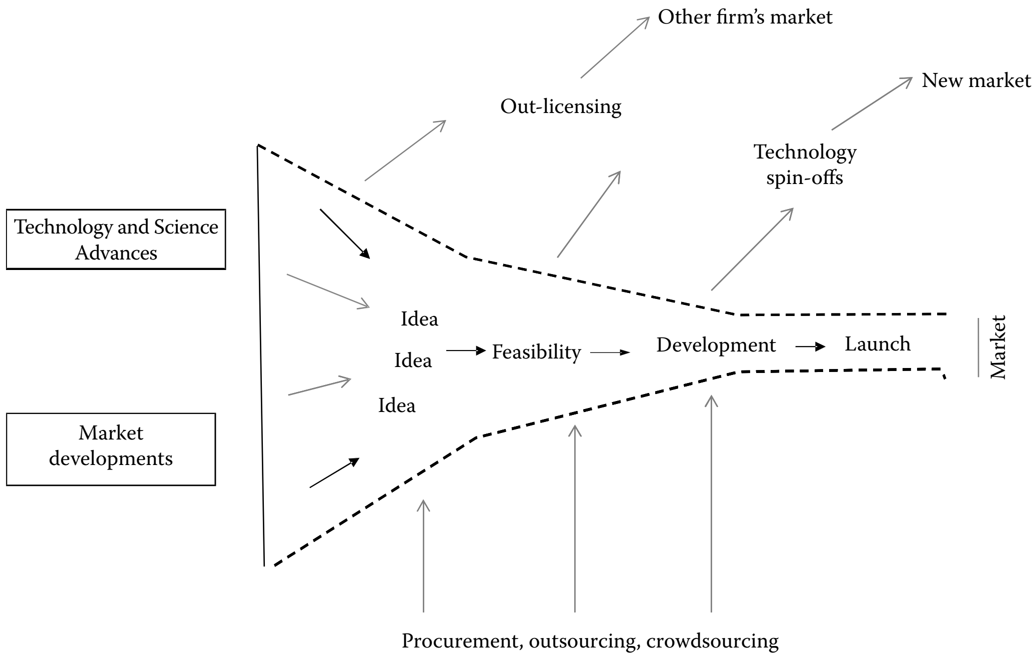

FIGURE 68.3 Open innovation funnel. (Adapted from Chesbrough, H., *Res. Technol. Manage*., 55(4), 20, 2012.)

funnel, the closed innovation process is a linear path from ideas to launch. Once fully developed, innovations are channeled to markets or used internally. The firm that creates the innovation is assumed to be in the best position to create value out of it (Kogut and Zander 1992; Wyld 2010).

For Chesbrough (2006), open innovation is about both decoupling and integrating the different phases of the innovation value chain and in so doing seeking radical innovation through business models. Open innovation is a paradigm shift "that assumes that firms can use external ideas as well as internal ideas, and internal and external paths to market" (Chesbrough 2003).

Figure 68.3 illustrates the innovation funnel adapted to open innovation (Gronlund et al. 2010). Ideas, opportunities, and technologies can come from internal or external sources and enter and leave the open innovation funnel at any stage. If the innovation fails one of the gates, it can take a different path and a different business model. Innovations do not just make their way through the firm's sales and marketing channels but as a spin-off, as out-licensing, as a design freedom, as an industry standard. There is a continuous assessment of external technologies, markets, and other developments. There is a continuous assessment of exportation and importation of know-how and technology. The gates are not just cost and risk evaluations but opportunity assessments (Gronlund et al. 2010).

Chesbrough (2012) identified three conditions that must be met to take advantage of the open innovation: workforce mobility, internal R&D, and basic rules on IP. The conditions are important because no significant innovation progresses without people moving; creative abrasion requires the integration of external and internal innovation; and IP protection rules are needed for investors to be willing to invest beyond the nascent stage of an innovation.

A key contribution of Chesbrough's (2006) work has been to bring greater focus on the role of business models in innovation management. A business model is "a structural template of how a focal firm transacts with customers, partners, and vendors" (Zott and Amit 2008). A business model focuses on how the firm commercializes the innovations of others and commercializes innovations through others (Chesbrough 2006). Business models are a way to generate different pathways through the open innovation funnel (Chesbrough 2012). Rather than turning an innovation into a product or service

that the firm sells, the firm can think of a different business model. Open innovation often means getting more aggressive about IP-based business models that involve leveraging technology from outside (e.g., in-licensing) or getting others to leverage the firm's technology (e.g., out-licensing).

Chesbrough (2006) argues that the most valuable open business model involves a platform. Platform refers to a system and architecture where a complex system is partitioned into stable core components ("platform"), variable peripheral components ("complement"), and standard interfaces (Baldwin and Woodard 2009; Gawer 2009). Complements provide variability and dynamicity through morphing and mutation. An example of such a platform in mobile technologies is the Android based platform by Open Handset Alliance (Han et al. 2012). In a platform-based model, the company's business model is interconnected with the business models of its key suppliers and customers. Not just the firm but all partners can innovate and share technical and financial risks and rewards. The IP is managed as a strategic asset.

68.3.2 Beyond Chesbrough on Open Innovation

Chesbrough's views have been highly influential but do not represent the only views regarding open innovation. During a paradigm shift, heated debates are expected. The definition and conceptualization of open innovation are still under much discussion (see recent commentaries by Linstone 2010; von Hippel 2010; Lichtenthaler 2011; Chesbrough 2012). We highlight some of these views as follows:

User innovation: To von Hippel (2005), the open paradigm shift is about changing functional relationship between innovator and innovation. In the past, producers were assumed to be the innovators who sold their innovations to users. Now, users innovate by improving and reinterpreting products and services through "sticky information" from repeated use. For example, users renegotiated the *Wii* gaming platform as an in-house exercise platform (Verganti 2009). In some areas as in sports equipment and software design, user innovation does not just complement but competes with producer innovation.

Private-collective innovation: von Hippel and von Krogh (2003) advanced the private-collective innovation model based on their research on open source. The model relies on a group of individuals and organizations collaborating and sharing their private ideas and knowledge and openly revealing innovations: yet gaining higher profits than free riders (von Hippel and von Krogh 2003). The private-collective model of open innovation relies on private investments, open revealing, and tacit learning to iteratively co-create and disseminate the innovation. As some tacit learning remains private, the innovators profit economically from their innovations.

Process transformation: Gassmann and Enkel (2004) promote transformation of three core processes in open innovation: (1) the outside-in process (wide and deep external search and integration), (2) the inside-out process (multiple channels for externalizing innovation including third party commercialization of innovation), and (3) the coupled process (combining outside-in and inside-out by collaborating in strategic networks with other companies). The coupled process requires strategic choices to participate in networks and share IP with other organizations and capabilities and resources to engage in intensive interactions to transfer learning across organizational boundaries.

Organizational permeability: For Dahlander and Gann (2010), openness is about "the permeability of firms' boundaries where ideas, resources, and individuals flow in and out of an organization" (p. 699). Open innovation is about openness in the inbound and outbound processes. The outside-in process of acquiring and inside-out process of selling involve monetary transactions. The outside-in process of sourcing and inside-out process of revealing are non-pecuniary.

Modularity: Baldwin and Clark (2006) and Henkel et al. (2012) emphasize modularity and architectural design decisions to enhance open innovation generation and appropriability (i.e., profit making). Modularity in design refers to the designers being able to design parts independently but working together to support the whole (Baldwin and Clark 2006). Modularity facilitates collaborating with diverse partners with different and even conflicting motives. Modularity can help a group of companies such as a consortia

or alliance to jointly develop the concepts for the innovation but then compete to privately appropriate the value (Ritala and Hurmelinna-Laukkonen 2009; Almirall and Casadesus-Masanell 2010; Han et al. 2012).

Disruptive change: A disruptive innovation creates new markets and business models and disrupts and eventually displaces existing technologies, processes, prevailing power and control structures, and institutionalized routines (Christensen 1997). Christensen et al. (2005) view open innovation as a disruptive change. Many unknown and unknowable factors face organizations embracing open innovation. They quote Paivitt (1999) to illustrate the type of uncertainties and ambiguities present, "In many areas, it is not clear before the event who is in the innovation race, where the starting and finishing lines are, and what the race is about."

IP management practices: Pisano and Teece (2007) argue that open innovation makes it much more challenging for firms to capture value (profit) from innovation. Open innovation requires much greater attention and skillful use of IP mechanisms such as patents, copyright, and secrecy in innovation management (Pisano and Teece 2007). At times, IP management is overly emphasized to the point that IP becomes a bottleneck for open innovation (Alexy et al. 2009).

Networks: Open innovation is about network-based innovation. Organizations increase their capacity for open innovation by participating in networks and improving their ability to learn from their partners (Fey and Birkinshaw 2005). However, without continual change in such networks, networks can become as much an obstacle as an enabler of innovation—"the ties that bind may become the ties that blind" (Birkinshaw et al. 2007, p. 68). Building new networks requires right attitudes and resources. It requires engaging in finding, forming, and performing in a wide range of networks. Such networks may include idea networks, funding networks, user innovation networks, cross-industry consortia, etc. (Birkinshaw et al. 2007). Companies have to be highly agile in building networks as there is much uncertainty and ambiguity in new ties.

To recap, we take an inclusive view into the open paradigm in innovation management. The views of Chesbrough and the aforementioned authors are presented and discussed to show that open innovation is multifaceted and complex.

68.3.3 Openness in the Open Innovation Paradigm

Openness is a common theme in the views of open innovation. However, what this openness is and represents is still much under debate. Many have pointed out that the antithesis of open innovation and closed innovation is largely a myth. Throughout history, firms have tapped external sources for innovation including Edison's laboratory in nineteenth century (Mowery 2009). Allen (1983) described the history of the nineteenth century iron and steel industry as collective. Process industries such as chemicals and oil and gas have a long history in relying on external sources of knowledge and technology (Lamoreaux and Sokoloff 1998).

In studying platforms, West (2003) was one of the first to raise the question of "How Open is Open Enough?" He found that in many industries, the industry pioneers initially developed proprietary and vertically integrated platforms to capture profits and protect against imitation (e.g., IBM's 360). Major technical and economic reasons moved the companies to offer more partly open platforms to seek interoperability and attract complementary business. In the partly open platforms, the commodity layers were open and those parts that offered differentiation were retained as proprietary. In a later work, West and O'Mahony (2008) defined "openness" via three indicators: (1) transparency (external parties able to contribute to the innovation), (2) accessibility (external parties able to influence the direction of the innovation), and (3) joint appropriation (external parties have use/development rights). They found that company-sponsored open source communities were more likely to offer transparency than accessibility. Transparency allowed external partners, or complementors, to participate on the platform but limited accessibility and maintained company control over key decisions. In a study of mobile computing platforms, Boudreau (2010) found that granting platform access to independent complementors was preferred over giving up formal company control of the platform itself.

Examining the outside-in process and specifically external search in innovative activities, Laursen and Salter (2006) defined openness in terms of breath and depth of sources. Breadth of external search was defined as the number of different external sources or search channels. The depth was defined in terms of the extensiveness to which firms deeply engage the external sources or search channels. Laursen and Salter (2006) found that those firms that searched both wide and deep were more innovative but only to a point where openness became subject to decreasing returns.

Again focusing on the outside-in process, Drechsler and Natter (2012) built on the Laursen and Salter's (2006) study by examining the underlying drivers of breadth and depth of external search in innovative activities. They found that different factors impact the initial opening of the outside-in process from those that lead the firm to further increasing the openness in the external search. Closed firms that did not engage in external search lacked internal capabilities particularly in the area of market and technology know-how and IP protection. They also faced much rivalry and imitation. The firms that increased openness in the external search were exposed to financial funding opportunities. They also developed effective IP protection mechanisms. This study underscores the internal company competence development both in terms of moving from closed to open and increasing openness.

Dahlander and Gann (2010) conducted a broad review of the open innovation literature to identify a typology of types of openness. They introduced a framework of openness that distinguished activities by their non-pecuniary and pecuniary character and the phase of innovation (outside-in process and inside-out process). Sourcing is the use of external information but without direct monetary payment. Acquisition (i.e., outsourcing) refers to purchasing resources from the market. Revealing is disclosing information without immediate financial rewards whereas selling (e.g., out-licensing) involves monetary exchange. Dahlander and Gann's (2010) review suggests that most studies so far have only examined one or at most two types of openness. Dahlander and Gann called for more research.

Openness also varies by innovation life cycle. In a study of open alliances, Han et al. (2012) speculated that openness is likely to be highest at the early stages and once ideas develop into products and services, with more certainty of markets and customers, openness will be adjusted to minimize spillovers, particularly to rivals. They also propose the possibility that as the products and services become mature, openness might be increased to gather improvements that further extend the life of the offering.

In summary, the discussion of openness has moved beyond a dichotomy to discussing openness by degree, type, and life cycle of the innovation. While no models exist in terms of optimal openness, research is beginning to define some boundaries for openness.

68.4 Open Innovation Forms and Approaches

Openness is impacted by the forms and approaches taken in a particular initiative. According to Huizingh (2011, p. 3), "open innovation [has] become the umbrella that encompasses, connects, and integrates a range of already existing activities." Baldwin and von Hippel (2011) also highlight how open innovation is based on combinations of existing techniques. Next, we highlight some popular forms and approaches. These are mapped to the innovation value chain (Figure 68.4).

68.4.1 Outsourcing of Innovation

Outsourcing of innovation represents limited openness. Companies procure, acquire, and in-license innovation from outside using contractual transactions. Outsourcing of innovation often represents something that the firm may have innovated internally in the past but now is left to another company or entity to innovate and the firm buys or acquires the innovation for a fee. Outsourcing of innovation includes sponsored research, strategic procurement, and development partnerships. While sponsored research addresses the idea generation phase of the innovation value chain, strategic procurement represents the diffusion phase of the innovation. The innovation is well developed with known characteristics.

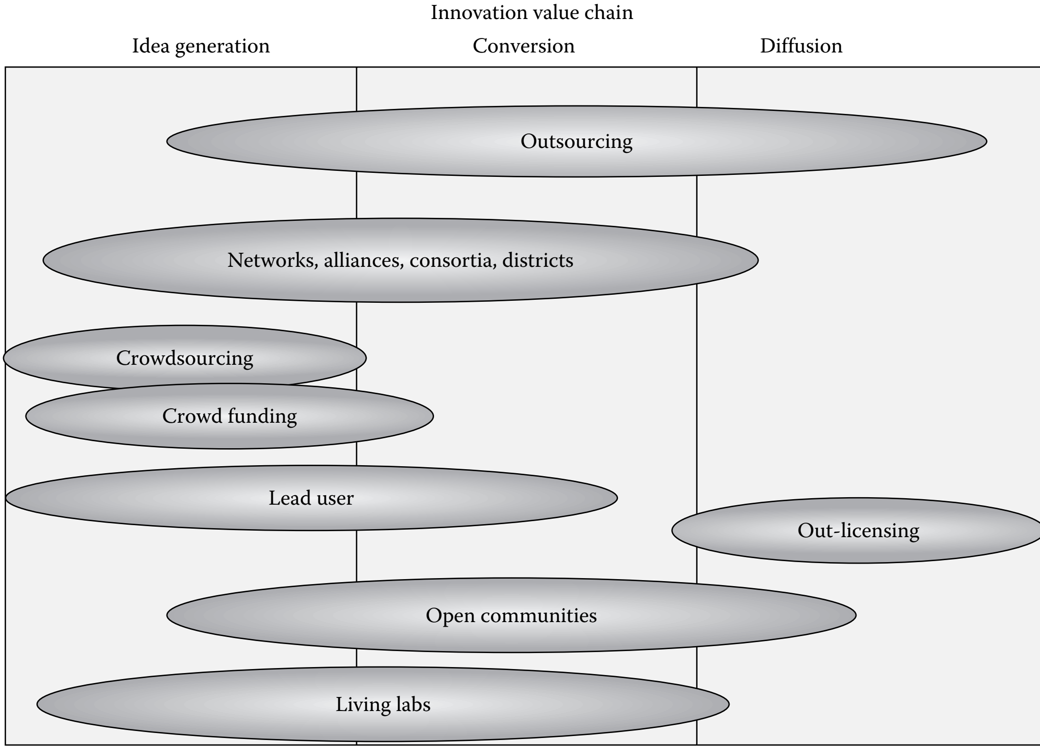

FIGURE 68.4 Illustrating open innovation forms on innovation value chain.

Many industries including the pharmaceutical industry have long turned to various forms of outsourcing of innovation to support their activities.

In 1996, Chesbrough and Teece (1996) asked "When is virtual virtuous?" that is, should firms outsource, namely procure and acquire innovation from outside partners just as they have outsourced production? At this point, the authors cautioned against outsourcing innovation when innovation relates to the firm's core competencies and involves architectural innovation such as platforms.

Linder et al. (2003) conducted a study in 2002 and examined the increasing portion of innovation that is externally sourced. They found that the share of innovative ideas from external sources was accounting for an average of 45% of ideas and the executives expected this percentage to grow. Retail companies reported as high as 90% of innovation from external sources. Shared risk, reduction in costs, and increased growth drove companies toward outside sources of innovation. Linder et al. (2003) found that many firms failed to realize the benefits from outsourcing activities because of a fragmented and project-based approach that lacked a coherent and holistic organizational strategy.

68.4.2 Consortia, Alliances, Networks, Clusters, Districts

Compared to outsourcing of innovation that involves bilateral contractual relationships, firms band together to save costs, share risks, and form larger multilateral relationships such as consortia (Pisano 2006). These are still contract based, but the membership can vary from stable (e.g., significant penalties for premature termination of contracts) to highly dynamic (e.g., open innovation alliances). This is a popular approach to innovation in the oil and petroleum industries, as well as automotive and chemical firms. The life science industry is well known for its clusters (Powell et al. 1996; Bunker-Wittington et al. 2009). Regional and national policy makers incentivize consortia as a way to revitalize or grow new, emerging industry sectors such as clean energy (Jaegersberg and Ure 2011).

Just as in outsourcing of innovation, there is a high level of variance within and across these multilateral relationships. Consortia that represent a "perfect community" with a strong shared identity that openly shares data, knowledge, and results can fail to transfer and commercialize innovations (Gibson and Rogers 1994; Cassier and Foray 2002). When competitors are part of the consortia, the work is divided and structured with clear roles and responsibilities by domains and technologies. Sharing is limited to predetermined areas with little accumulation of knowledge pools. Ownership rights are handled separately by different participants. There is minimal contact by personnel from rival companies. At times, work does not go beyond defining the future research areas as was the case with a breast cancer research consortium (Cassier and Foray 2002).

Open alliances (e.g., Android) represent groups with competing entities with dynamic membership. Open alliances "seek to enlarge the 'economic pie' through value co-creation, rather than fighting with competitors over a 'fixed pie'" (Han et al. 2012). Han et al. (2012) reported that participating firms realized significant positive returns particularly when the alliance engaged in radical innovation. However, rival firms who did not participate in the alliance gained even greater benefits through free riding.

68.4.3 Crowdsourcing and Sponsored Co-Creation

Crowdsourcing involves a job or activity that would have been traditionally performed by an employee or outsourced but now performed by a large group of people, or crowd, in the form of an open call (Howe 2006). Crowds are expected to provide unbiased information ("wisdom of the crowds"). The Internet and collaboration technologies have created opportunities to expand the crowd and use it to perform innovative tasks (Albors et al. 2008; Afuah and Tucci 2012). Sponsored co-creation shares many similarities with crowdsourcing but is often less time paced and less structured (Nambisan and Baron 2010). Crowdsourcing and sponsored co-creation are in widespread use across industries (Bogers et al. 2010). Openness is limited. While anyone can propose an innovative solution, the sponsor proposes a problem and claims ownership rights to the solution.

The Threadless example mentioned at the beginning of this chapter is an example of crowdsourcing. Threadless' design contests allow customers to submit new t-shirt ideas for a chance at prize money. Goldcorp of Canada used the crowd to locate the position of gold on its properties. Dell's IdeaStorm is a firm-sponsored crowdsourcing community. In 2007, the firm launched the site as a way to counter negative feedback toward its business model. The site was introduced with the statement that IdeaStorm was a place "where your ideas reign" (di Gangi et al. 2010, p. 215). Users can post improvement ideas for Dell's products and services and other users can promote or demote the ideas. Users are not given a financial incentive but top users are honored on the Top Idea Makers List.

Tournaments are a common form of crowdsourcing: "each agent from the crowd self-selects to work on its own solution to the problem, and the best solution is chosen as the winning solution" (Afuah and Tucci 2012, p. 355). Netflix used a tournament-based form of crowdsourcing to improve its movie recommendation system. Darpa Grand Challenge and Google Lunar X Prize are other well-known examples. Procter & Gamble, as part of their "Connect and Develop" model, launched NineSigma, a crowdsourcing intermediary that runs tournament-based crowdsourcing (Jeppesen and Lakhani 2010). Procter & Gamble initially set up Innocentive to address internal R&D problems and then turned it into a separate business. Innocentive and other intermediaries attract companies as they can reduce costs of finding solvers, reduce costs of specifying what is needed, and facilitate enforcing rules and agreements. Jeppesen and Lakhani (2010) found that people in fields outside of the problem domain often become successful solvers in tournaments; the distance between the solver's field of technical expertise and the field of the problem owner increased the likelihood of winning; female solvers performed significantly better than men in developing successful science solutions. There are also platforms that facilitate contests inside large and distributed global firms, for example, Innocentive@work.

Crowdsourcing is also used for big social problems. Founded in 2010, the OpenIDEO platform was launched by a global design firm, IDEO. The platform invites anyone in the world to enjoy solving

problems associated with social issues. The platform has hosted 16 challenges and 35,000 participants had participated by August 2012. A key incentive is to do social good while staying on your sofa. The OpenIDEO platform does not award prizes. The platform uses IDEO's unique approach to problem solving (Lakhani et al. 2012).

Motivational represents the biggest challenge. The heterogeneous motives and backgrounds make it challenging to motivate and support the participants (Antikainen et al. 2010). Füller (2010) listed a variety of motives including extrinsic reward-oriented, need-driven, curiosity-driven, and intrinsically interested. It is this heterogeneity that makes it challenging to activate and sustain an active community over time (Leimeister et al. 2009; di Gangi et al. 2010; Zheng et al. 2011). Many companies find that they face a major battle trying to sustain co-creation (Jarvenpaa and Tuunainen 2012). The use of awards might crowd out contributors. On sponsored co-creation sites, the frequent contributors may be explicitly identified from less frequent contributors. Even this type of recognition can crowd out participants (Gu and Jarvenpaa 2003). Besides explicit recognition, there are often no immediate benefits except the crowdsourcing or co-creation experience (Nambisan 2002; Nambisan and Baron 2010).

Another challenge is to find the problems that actually can be solved with crowdsourcing. Afuah and Tucci (2012) identify several requirements: Problems need to be easily delineated and modular. Solutions need to require knowledge that is far from what the problem owner currently has available. The crowdsourcing needs to reach a motivated crowd that has problem-solving skills. If the crowd is expected to vote, then the solution has to be appraisable by multiple people.

68.4.4 Crowd Funding

An extension of crowdsourcing is crowd funding. Crowd funding is a collective effort of users or consumers to pool their money together and invest and support an initiative (Ordanini et al. 2011). New funding platforms such as GrowVC collectively fund innovation by opening the opportunity to invest small amounts of capital or effort ("sweat equity") to start-ups around the world. Besides providing funds, they can signal the initiative's market potential and expect their feedback to be heard as the ideas are refined and improved. Voting with money is expected to lead to more thoughtful and credible input and an improvement over traditional crowdsourcing. Crowd funding initiatives can reduce costs of initial development, create visibility, and encourage word of mouth marketing, and even drive initial sales for a new initiative or project idea (Burtch et al. 2012). However, here again, heterogeneous motives make management of the process difficult. Sometimes a crowd can be uninformed, driven by herd behavior, or not understand the initial idea. This then leads to a noisy signal problem in the ideation marketplace. The use of crowd funding is in its infancy and failures are still very common (Burtch et al. 2012).

68.4.5 Lead User

In the lead user approach, it is the user that identifies the problem to be solved and creates the solution (von Hippel 1977). The lead user approach is premised on the idea that users have the most accurate assessment of their needs and hence are ideally suited to be the innovators (von Hippel 1986). Compared to traditional ways, the lead user method has been identified as a much faster and cheaper way of identifying new product concepts (Herstatt and von Hippel 1992). Lüthje et al. (2005) found that users with membership in multiple communities were able to combine previously disparate information; the lead users of mountain bikes were medical doctors who wanted to make bikes safer (Lüthje et al. 2005). IP issues are deemphasized with the lead user approach. The lead users are not usually interested or concerned about protecting their innovations (Shah 2000).

The lead user innovator approach is most applicable in the context of complex products and services involving complex systems that require high levels of customization, iterative design, and adjustment after purchase to meet heterogeneous customer demands. The challenge for the firm is to locate the lead

users that operate at the world-class level and identify innovations that have commercial value in the marketplace (Bogers et al. 2010). The firm may provide tool kits to encourage this type of innovation (Franke and von Hippel 2003; Jeppesen and Frederiksen 2006). Toolkits for user innovation allow customers to discover their needs in a structured fashion that enable users to develop new innovations (von Hippel and Katz 2002). The toolkits are specific to a certain design area such as software design (Franke and von Hippel 2003).

68.4.6 Open Community Innovation

Just like the lead user model relies on a non-pecuniary relationship, so do open communities for innovation. There are no legal transactions involved. Whereas the lead user model is driven by the user's private benefit, the open community innovation is driven by generalized reciprocity and community norms (Wasko and Faraj 2000; Roberts et al. 2006). The model relies on open reveling: instead of claiming proprietary rights over the proprietary knowledge that they have, community participants allow others to freely use their knowledge in the community (von Hippel and von Krogh 2006). Open revealing is associated with superior learning opportunities that still allow private benefits such as learning, enjoyment, and reputational gains (Henkel 2006).

There are a multitude of open source communities. Technology open source communities include Linux, GNOME, Apache, and Mozilla. Wikipedia (O'Mahony 2003; Niederman et al. 2006) is another open source community. There are various sporting communities such as kayaking, snowboarding, windsurfing, skateboarding (Franke and Shah 2003), and there are even music remix communities (Jarvenpaa and Lang 2011). The communities are usually characterized as low in rivalry although Franke and Shah (2003) found that even when there is rivalry, assistance is still given and innovations are revealed although not "just not as often as in the less competitive communities" (p. 172). Although the open community can represent radical innovation in its own right such as Wikipedia, particular innovative outputs are often a result of independent entities (firms or individuals) providing incremental contributions.

Challenges relate to finding new contributors and maintaining dynamicity (Faraj et al. 2011). Continuous changing membership, ambiguous identities, rotated leadership, and various technology affordances among other things can maintain necessary dynamics in innovative activities (Faraj et al. 2011). Challenges also relate to building sufficient actionable transparency (Baldwin and von Hippel 2011). Modular architectures and collaborative spaces facilitate such transparency and allow thousands of independent contributors to work independently and in parallel. Others' activities can be transparent without any direct communication taking place between the contributors.

68.4.7 Living Labs

Living labs are hybrid communities of lead user and open community innovation that have become popular in Europe and are particularly encouraged by public sector funders (Almirall and Wareham 2011). Living labs involve an intermediary that brings together the users to engage in exploration (i.e., research), as well as others that are part of the technology implementation, to test out various exploitation options. Almirall and Wareham (2011) analyzed six living labs as part of the European Network of Living Labs. These cases involved media and health, as well as an industrial consortium in the automobile sector. Living labs were found to be valuable in arbitrating incremental innovation by bringing together disparate actors, creating user demand, and testing different business models. The challenges focused on connecting all the dots and coordinating the activities of heterogeneous actors in the innovation value chain.

68.4.8 Out-Licensing

An approach that encourages other companies' use of the firm's innovations includes out-licensing. Out-licensing generates new sources of revenue. Out-licensing can also promote learning of customer and other

firms' environments as licensing agreements do not just require legal transactions but also tacit knowledge exchange. Large companies such as IBM and Texas Instruments have had active out-licensing programs since the 1980s. Small companies also have adopted licensing as a key strategy. For example, Rovio has licensed its trademark Angry Birds to over 15,000 different products around the world. But for many companies, out-licensing strategies and activities are still in their infancy (Lichtenthaler 2011). Successful out-licensing programs require a strong involvement from senior management, a dedicated structure to house specialized knowledge and skills (e.g., licensing office, dedicated teams), as well as support and participation of the firm's employees (Lichtenthaler and Ernst 2007; Bianchi et al. 2011a,b). Firms often rely on outside intermediary services (e.g., law firms); however, they are best considered as complementing not substituting internal capabilities (Licthtenthaler and Ernst 2007).

68.5 Theoretical Perspectives to Open Innovation

Open innovation is fundamentally about the boundaries inside and outside the firm, management of knowledge and learning, social relationships, power, identity, and legitimacy. The existing research follows theoretical perspectives commonly used to study inter-organizational relationships (see Parmigiani and Rivera-Santos 2011).

The most common theoretical perspectives relates to the boundaries of the firm from an organizational economics perspective. Open innovation can reduce production costs, bring benefits in the form of complementary assets, and achieve greater incentive alignment through modular platform architectures. Organizational economics perspectives include theories of transaction cost economics (TCE), agency theory, network externalities, and the resource-based view (RBV).

TCE is used to understand when open innovation is a more efficient alternative than governing activities and transactions internally. According to Williamson (1991), the optimal organization of transactions should minimize the production, communication, and opportunity costs, and strive for scale and scope economies. Transactions should be handled internally when probability of opportunistic behaviors is high and coordination costs are substantial.

TCE is commonly used to frame theoretical arguments regarding why certain open innovation forms or approaches are becoming more common or viable (e.g., Cassiman and Valentini 2009; Lazzarotti and Manzini 2009; Baldwin and von Hippel 2011). Baldwin and von Hippel (2011) and Demil and Lecocq (2006) develop governance models for open community innovation (Baldwin and von Hippel 2011). Demil and Lecocq (2006) consider the open community model based on open license to be superior when there is extreme uncertainty, weak incentives, and low levels of control. Baldwin and von Hippel (2011) argue that the open community model is viable in areas where rivalry is low as there are no costs to maintaining secrecy.

Agency theory is defined as aligning incentives across different actors when ownership and control are separated (Eisenhardt 1989). When organizations employ agents to represent them, there are costs from differences in the goals of the organization and agents. Transparent architectures are theorized to reduce agency costs (Baldwin and von Hippel 2011). However, the existing literature on open innovation suggests that agency issues are difficult, unresolved, and poorly understood (e.g., West and O'Mahony 2008). There is also an attempt to develop new notions of agency (Ulhøi 2005).

Open innovation research regarding TCE and agency theory is conceptual or relies on small samples. Compelling empirical evidence proving that open innovation leads to effective governance models is limited or the results are mixed at best. Niederman et al. (2006) note that there is little evidence that open source is a superior form of governance from the efficiency perspectives. Baldwin and von Hippel (2011, p. 1404) limit their developments to "bounds on the viability." Some find that open innovation happens despite very high transaction costs (Christensen et al. 2005). Others (Remneland-Wikhamn and Knights 2012) question the use of transaction costs in shedding insight to open innovation. They argue that TCE has a limited descriptive power and potentially does normative damage to open innovation as the perspective does not consider the broader policy and cultural issues. TCE research in open

innovation also suffers from other weaknesses that are commonly associated in applying the theory to information technology–enabled forms. Information technology is rapidly reducing costs in all governance forms including vertically integrated forms. Moreover, information technology is increasing variety in all forms and so variations within forms can be as great as across forms.

68.5.1 Resource-Based View

RBV theorizes that firms are a bundle of resources and capabilities (Barney 1991). Whereas TCE assumes that resources and capabilities are homogeneously distributed across firms, RBV assumes heterogeneity and resource mobility across firms. Firms can develop firm-specific valuable resources, capabilities, competences, and dynamic capabilities, which can be leveraged for competitive advantages and favorably impact firm profitability.

Open innovation provides a way to source resources possessed by the partners, as well as acquire new resources via outsourcing. This, along with internal development, combines to produce uniquely configured capabilities that are valued in the marketplace. Open innovation requires that capabilities coevolve with the speed of market opportunities. The RBV helps explain why open innovation can boost growth via alliances and in-licensing of technology without acquiring the whole business. RBV also helps illuminate risks of open innovation. Open innovation presents risks of unwanted mobility of these capabilities or potential leakage of valuable knowledge to rivals (e.g., open alliances) (e.g., Han et al. 2012).

Case studies highlight the major challenges of employee training and a deep organizational change to deploy open innovation successfully. Chiaroni et al. (2010) studied the journeys of four different companies as they created an infrastructure for open innovation. The companies went through a deep organizational change. The companies developed inter-organizational networks (relationships with universities and outside research centers) and established new roles and skills (liaisons and gatekeepers). New organizational structures (e.g., IP office) were created and new evaluation processes, ICT systems (video conference), and knowledge and project management systems (develop patent filing systems) were implemented. To recap, open innovation presents the ability to tap to critical resources and capabilities outside, but the firm has to make major investments to develop the internal capabilities before the new combinations render imperfectly tradable resources and capabilities.

68.5.2 Absorptive Capacity

RBV suffers from focus on possession rather than the ability to deploy these capabilities. Deployment is the focus of absorptive capacity theory—a behavioral theory of the firm (March and Simon 1958). Absorptive capacity refers to the "ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends" (Cohen and Levinthal 1990, p. 128). Absorptive capacity depends on the existing stockpiles of knowledge and networks of contacts. The stockpile is a product of past and present managerial choices.

Christensen et al. (2005) found that to successfully leverage open innovation, firms have to have "the abilities or luck to exploit more or less coincidental opportunities emerging outside the boundaries of the firm" (p. 1547). Lichtenthaler and Lichtenthaler (2009) developed a capability-based framework for open innovation. They recognized different knowledge management processes are needed to identify, select, retain, transform, and exploit external and internal knowledge resources for innovation. One significant contribution of their work is the concept of "desorptive" capacity, opposite of absorptive capacity. Desorptive capacity refers to "identifying external knowledge exploitation opportunities and subsequently transferring the knowledge to the recipient" (Lichtenthaler and Lichtenthaler 2009, p. 1322). Desorptive capacity allows the firm to engage in external exploitation. Without desorptive capacity, the firm licensing the innovation will not transfer the necessary tacit knowledge for the licensee to exploit the innovation. The lack of exploitation can lead to reduced licensing revenues and reduced demands for the innovation by other firms. Robertson et al. (2012) developed another capability-based model for process industries that emphasizes deployment of

external and internal resources and capabilities. They identified three capacities: accessive capacity, adaptive capacity, and integrative capacity.

Just as with TCE and agency theories, RBV of the firm and absorptive capacities are mainly used to develop conceptual frames that explain why firms succeed in open innovation. Failure stories are sorely lacking—either as standalone or as contrasted with successful cases. Large-scale empirical examinations are hard to find. Dynamic perspectives are still rarely examined although with some exceptions (Han et al. 2012).

68.5.3 Network Externalities

The network externalities theory posits that a product or service becomes more valuable as its user base expands (Katz and Shapiro 1986). This implies that innovations that are associated with large networks will tend to attract more users due to a positive feedback effect (Katz and Shapiro 1994). Adding variety to the platform attracts more users to the platform. More users in turn attract more complementors such as application providers. However, research such as online communities and peer-to-peer file sharing networks have shown positive and negative effects of increased network size due to the additional resources and to increased free riding, congestion, and cognitive load (Asvanund et al. 2004; Butler 2001), suggesting that larger networks may not always provide more superior value.

The network externalities theory (Shapiro and Varian 1999) has been used to study how the owner of the technology should open up the development and commercialization of technology. Opening creates momentum and can attract larger user bases but the opening can also leave the original owner with little control and ability to appropriate value. Using a measure of innovation as the rate at which new handheld devices were introduced, Boudreau (2010) found that granting access to independent complementors to a platform was preferred over giving up formal control over the platform itself. Diversity appeared to be more important than incremental shifts in formal control.

The network externalities theory has been used to study how many complementors (e.g., software solution providers) and contestants should be invited to participate in the open innovation platform. Boudreau (2012) examined a leading handheld computer platform as a two-sided market and studied the number of application producers and the selection of software solutions. Consistent with the network externalities theory, he found that adding producers using different software systems tended to increase innovation incentives, consistent with network effects. However, adding producers created crowding of similar applications that in turn negatively impacted novelty. In another study involving a crowdsourcing tournament, Boudreau et al. (2012) found that as competitors to the contest increased, greater rivalry reduced the incentives of all competitors to exert effort and make investments.

68.5.4 Social Capital

Social capital theories take into consideration embeddedness (Granovetter 1993), connecting with other individuals and organizations, and gaining access to greater and more diverse sources of knowledge. An important question is what type of social capital, or embeddedness, promotes innovation. Relational embeddedness relates to strong ties, repeated interaction, and solidarity with the same partners (Coleman 1990). Relational embeddedness facilitates innovation through the transfer of tacit knowledge but suffers from not-invented-here because of blindness to group norms (Katz and Allen 1982). On the other hand, structural embeddedness, or the presence of structural holes and nonredundant ties, promotes access to a wide range of information sources (Burt 1992). Nonredundant ties increase unique information, the ability to be more informed of opportunities, and have more options for creating unique combinations that result in innovation. Rost (2011) found that both structural and relational embeddedness contributed to the creation of innovation. Individuals who were part of strong social circles but with ties to broader networks came up with more innovations. Relational and structural embeddedness were complements rather than substitutes.

Others have found that emerging leaders in open source initiatives exhibit both structural and relational embeddedness. Fleming and Waguespack (2007) found that emerging leaders were brokers (connected and disconnected actors), boundary spanners (served as technical leaders, knowledge links, respected guardians), and engaged in bonding (enabled community building and community benefit). du Chatenier et al. (2010) found it important for professionals working in open innovation teams to have similar skill sets.

68.5.5 Organizational Paradox Perspective

Researchers widely acknowledge that open innovation paradigm represents a complex balancing act of paradoxes, tensions, competing demands, conflicts, contradictions, and dilemmas (e.g., West and Gallagher 2006; Jarvenpaa and Wernick 2011). There are many tensions in open innovation including balancing how internal innovation units compete for resources with external sources (Chesbrough and Garman 2009). There is the tension between losing control over proprietary knowledge and technology yet the importance of sharing for the benefits of collectivity (West and Gallagher 2006). Almirall and Casadesus-Masanell (2010) examine the trade-off of open and closed approaches to innovation: They find that when complexity is not too high, open innovation is preferred to closed innovation. Yet, the literature has rarely gone beyond recognizing the tension that exists regarding open and closed innovation and how to transcend it in a mutually reinforcing way.

The organizational paradox perspective (Smith and Lewis 2011) is a promising theoretical perspective that has yet to be fully exploited in open innovation research. It is based on dialectics and duality (Farjoun 2010). Paradoxical perspective differs from both TCE and RBV. In simple terms, where TCE focuses to minimize distrust to reduce coordination and opportunity costs and RBV focuses to maximize trust as an organizational capability, the paradoxical perspective argues that value arises from simultaneously maintaining both trust and distrust. This is because trust alone conceals complex mixed motive inter-organizational relationships that require vigilance. Distrust without trust leads to withdrawal from collaboration (Jarvenpaa and Majchrzak 2010).

The paradox perspective treats what is traditionally considered as trade-offs, as something that has to be managed in an integrative fashion (Jelinek and Schoonhoven 1990; Dougherty 2006; Bledow et al. 2009). For example, exploration versus exploitation and radical versus incremental are often viewed as alternatives rather than as something that is embraced simultaneously. The organizational paradox perspective argues more effective outcomes can be achieved if the seemingly contradictory principles or practices are juxtaposed so they remain independent but mutually enabling (Lewis 2000; Smith and Lewis 2011). Success is increased if the firm simultaneously attains exploration and exploitation rather than one over the other or in alternating sequence.

Several theoretical perspectives were reviewed that are present in the open innovation literature. The organizational paradox perspective was presented as a new promising theoretical basis.

68.6 Research Questions

Throughout this chapter, gaps in the current literature are identified. The gaps are also well highlighted in the existing literature. For example, West and Gallagher (2006) identified fundamental challenges in open innovation: (1) What internal resources and capabilities should be shared with the networks? (2) What is the best way to search, discover, and integrate external sources and innovations internally and then best exploit these new innovations in various external markets? and (3) How to motivate the various parties in the network, internal and external, to share their resources and capabilities when the outcomes of these efforts may be available to rivals? How do firms make choices in accessing external knowledge and protecting their own knowledge? Enkel et al. (2009, p. 312) summarized the situation: "we still lack a clear understanding of the mechanisms, inside and outside of the organization, when and who to fully profit from the concept."

Traditionally, there has been a need to gain a better understanding of the costs (transaction costs and production costs) of open innovation and how information technology affects costs. What are the theoretical underpinnings of different open innovation forms and approaches? Following Baldwin and von Hippel (2011), what are the conditions under which these models become viable? We conclude with few questions.

68.6.1 What Are the Bounds of Effective Open Innovation?

Open innovation has been heralded as decreasing the risk of missing market opportunity, not reinventing the wheel, increasing learning, lowering costs, turning customers and users into producers, building broader and deeper networks, and engaging community building. Open innovation is not inherently superior to traditional innovation and is associated with many hazards. However, the boundaries of effective open innovation are still uncertain. Therefore, more research is called for to explore the new frontier of open innovation thereby enabling forward looking firms to put the research into practice.

The viability of open innovation can be examined from the view of transaction efficiency, capability development, social tie formation, and others. Integration of multiple theoretical perspectives should be considered to continue to gain insight into open innovation.

68.6.2 How to Design an Organization for Open Innovation?

A relevant question to ask is: What are the organizational design principles for open innovation? Acha (2008) makes the compelling case that "design shapes open innovation practice." Design can also shape the viable forms and approaches. A key concept in design is task partitioning that reduces the cognitive burden of complexity and allows work to be conducted in parallel (von Hippel 1990). Design is also important for horizontal and self-managing control (O'Mahony and Bechky 2008; Dahlander and O'Mahony 2011). However, design has been given little attention apart from the platform-based studies (Gawer 2009). Design science approaches and methods can and should be leveraged to develop and compare alternative designs (Hevner et al. 2004).

68.6.3 Is Open Innovation about Incremental or Radical Innovation?

A pertinent issue in the open innovation literature is whether the open paradigm promotes radical innovation or continuous improvement. To Chesbrough (2006), a move to open innovation is seen as a way to create discontinuity with the past as new business models create fundamental change. However to others, open innovation is about business experimentation and replication (Davenport 2009; Brynjolsson and Saunders 2010). Experimental approaches reduce the length of the development cycle, making changes continuous and more easily adopted and diffused. The continuous experimental innovation process leverages the capture, measurement, analysis, sharing, and replication capabilities of information technology (Brynjolfsson and Saunders 2010). Davenport (2009) coins it as a "Test and Learn Wheel." Amazon and Google run thousands of experiments daily. Many software companies are using open developer communities to modify, test, and release software in fast cycles. While these innovation outcomes are small, the innovation process itself is revolutionized by information technology (Brynjolfsson and Saunders 2010).

68.6.4 What Is the Role of Information and Communication Technology?

Technological changes have been key drivers as well as enablers of open innovation forms and approaches. ICT has provided ubiquitous global infrastructures that enable the firm to tap into distributed sources of information wherever it exists. Dell used a crowdsourcing platform, Salesforce CRM for its IdeaStorm (di Gangi et al. 2010). Brynjolfsson and Saunders (2010) identify a number of ways that

ICT facilitates innovation. ICT increases productivity and efficiency of transactions. It spurs innovation including new management techniques, business models, work processes, and human resource practices. ICT is changing the way innovation is performed making possible real-time and cost-effective business experimentation and replication where observations are shared and ideas are gathered widely. Dodgson et al. (2006) examined the technological development underlying Procter & Gamble's connect and develop strategy. In this case, ICT was particularly important in enabling data searching, mining, simulation and modeling, and virtual and rapid prototyping. Yet, there is again of paucity of research examining how IT affects failure and success of open innovation, different degrees of openness, and how it affects radical versus incremental innovation in a wide range of contexts. In most studies on open innovation, ICT has taken a nominal role (Orlikowski and Iacono 2001, p. 121): "The IT artifact itself tends to disappear from view, be taken for granted, or presumed to be unproblematic."

68.7 Concluding Note

This chapter covered the emerging open paradigm in organizational innovation management. Several key concepts from innovation management were introduced that are particularly relevant in terms of open innovation. Multiple views regarding open innovation were presented along with emerging notions of openness. Some forms and approaches of open innovation were reviewed. Various theoretical perspectives were briefly highlighted. This chapter concluded with research questions.

Inter-Organizational Information Systems

Charles Steinfield
Michigan State University

69.1 Introduction

Nearly all modern organizations rely extensively on computer-based information systems to process the data needed to operate their businesses for such tasks as managing employee data, keeping track of sales and inventory, engaging in product development, forecasting future demand, and maintaining customer information. When such information systems extend beyond the borders of one organization and provide for automated information exchange to support linked business processes between two or more organizations, they are considered to be *inter-organizational information systems* (IOS) (Robey et al. 2008). IOS have become increasingly prevalent in the networked world in which businesses operate today. Often these systems are used to connect suppliers and manufacturers to support *just-in-time* (JIT) inventory practices in *supply chains* based on *electronic document interchange* (EDI), a global standard for structured exchange of business data and documents. In the retail sector, *collaborative planning, forecasting, and replenishment* (CPFR) systems are used to improve coordination up and down the value chain of retailers' supply partners, so that suppliers are better aware of consumer demand and retailers can better manage replenishment practices and inventory costs. Moreover, electronic procurement has become pervasive in business-to-business (B2B) exchanges, promoting widespread use of IOS in nearly all types of industries.

The study of IOS has emerged as a distinct area within the broader field of information systems in large part due to the many challenges organizations face when they attempt to implement and use IOS (Markus 2006; Steinfield et al. 2011). Since IOS by definition includes two or more organizations, decisions to adopt, implement, and use IOS are not independent decisions made by one firm and can be influenced by a wide range of factors such as power differences between companies, the degree to which trading partners trust each other, or participants' long-term strategic goals (Robey et al. 2008). In contrast, the management of an internal information system is usually under the control of one organization, simplifying the processes of adoption, implementation, and use. IOS also face

inter-operability challenges, since the internal systems of the participating organizations may be based on incompatible and/or proprietary formats (Markus et al. 2006). This chapter provides an overview of the study of IOS, examining the basic types of IOS, implications for practice, and key research questions. An overarching theme of this chapter is that IOS are socio-technical systems, where the combination of technical choices, organizational practices, relational factors, and industry context all influence outcomes of IOS use.

69.1.1 Types of IOS

IOS as a distinct management concern and subject of study began to appear in the early 1980s, with researchers describing and categorizing inter-organizational information sharing systems and their related management concerns (Barrett and Konsynski 1982; Cash and Konsynski 1985). Early IOS were often simple remote ordering systems between trading partners in adjacent steps in a value chain (a manufacturer ordering parts from a supplier, a retailer ordering inventory from a manufacturer, or a travel agent reserving a seat for a client on an airline). More complex and higher-level systems involved more partners, additional business functions, and greater integration of business processes across separate trading partners (Barrett and Konsynski 1982).

69.1.1.1 Electronic Hierarchies and Electronic Markets

One early classification of IOS distinguished between systems connecting a buyer with a specific seller in a hierarchical relationship—termed an *electronic hierarchy*, and systems that connected buyers with a larger set of potential sellers—termed an *electronic market* (Malone et al. 1987). This distinction emphasizes two types of control that govern the behavior of the participants in the IOS. In the case of electronic hierarchies, there is an implication of longer-term, stable business relations, where managerial and/or contractual relations will ensure that the potential for opportunistic behavior, such as providing substandard goods or services, is controlled. In electronic markets, however, market forces and exchange partners' ease of switching to new trading partners provide the necessary *governance* over the behavior of participants in order to reduce the potential for opportunistic behavior (Malone et al. 1987).

Other types of IOS that do not fit so neatly in the electronic hierarchy–electronic market continuum are evident. For example, an ATM network like Cirrus, where the IOS is controlled by a network facilitator that is mainly in the IOS business, rather than set up by a company that is selling the core products and services carried by the network is another form of IOS arrangement (Grover 1993). Choudhury (1997) further extends the electronic hierarchy–electronic market classification to account for the strategic relationships embodied in an IOS, describing three types of linkage patterns: (1) electronic monopolies—where buyers can only obtain a particular good through one seller's IOS, (2) electronic dyads—where buyers establish separate electronic links with a number of different sellers, and (3) multilateral IOS, where buyers and sellers use a shared system for transactions that more closely correspond to spot market purchases.

69.1.1.2 Horizontal, Vertical, and Cross-Linkage IOS

IOS can further be classified according to the industry structure aspects of relationships among the participants—horizontal, vertical, and cross-linkages (Hong and Kim 1998). Those that link businesses that are in adjacent steps in a value chain—where each business progressively adds value to a product or service—can be thought of as vertical IOS. Vertical IOS are best exemplified in supply chain information systems linking suppliers to manufacturers and perhaps to distributors and retailers where the participants are in a dependent relationship with each other. Horizontal IOS link companies that operate at common stages of the value chain, where each company performs similar value adding activities. These are often found in more cooperative forms of business relationships such as alliances or partnerships. Cross IOS span vertical and horizontal dimensions linking both buyers with each other, as well as to sellers at different stages in the value chain (Hong and Kim 1998).

69.1.1.3 Standards-Based versus Proprietary IOS

Recent work extends these earlier typologies by making three additional types of distinctions: (1) proprietary versus standards-based IOS (Markus et al. 2006; Nelson et al. 2005; Zhu et al. 2006), (2) point-to-point configurations versus hub-based architectures linking participants in a supply chain, and (3) IOS systems that are closed and private versus those that are shared and open to new participants (Steinfield et al. 2011). The push toward standards-based IOS has been driven by the rapid expansion of the Internet and associated protocols such as XML into business data networks, making it easier for businesses to interconnect electronically with an ever-larger proportion of trading partners without the need for investment in new proprietary systems for each individual partner (Markus et al. 2003). Over the past decade, data-exchange standards have been developed in a number of different industries, often driven by trade associations and other voluntary industry consortia. Examples include RosettaNet in the electronics industry (Boh et al. 2007), MISMO in the home mortgage industry (Markus et al. 2006), and ACORD in the insurance industry (Jain and Zhao 2003).

69.1.1.4 Point-to-Point versus Hub-Based IOS

The distinction between point-to-point versus hub-based systems has been used to shed light on the fundamental question of *visibility* in supply chains (Steinfield et al. 2011). Lack of visibility in extended supply chains is associated with many information distortions faced by participants leading to such classic coordination problems as the *bullwhip* effect (Lee et al. 1997). Bullwhip effects occur when variations in orders propagate up the supply chain as each company builds in its own buffer inventory under conditions of uncertainty about actual demand, yielding larger and larger variations from actual sales data the further one goes up the chain. Since point-to-point systems only connect one supply participant to another, information about each transaction is not visible to other supply participants, even though they may benefit from having such information. Imagine the situation, for example, when a lower tier supplier experiences a delay in shipping crucial parts to a higher tier assembler. This will in turn impact the availability of completed assemblies to the manufacturer, but if information only flows through separate point-to-point systems, the manufacturer may not be made aware of the delay until later, when it may be too late to adjust production schedules. If the supply chain participants were involved in a hub-based system with appropriate business rules for sharing information about supply chain events, then the manufacturer would know about the delay immediately and can plan accordingly. Such an approach is under development in the automotive industry. This approach, known as the Materials Off-Shore Sourcing standard, is designed as a hub-based system where shipment information is simultaneously made available to the relevant participants as soon as events occur (Steinfield et al. 2011). More broadly, hub-based approaches can support greater collaboration among supply chain participants, as opposed to primarily providing transaction support (Markus and Christiaanse 2003).

69.1.1.5 Open and Shared versus Private IOS Hubs

A final distinction is whether IOS systems are shared and open to new participants or are private and limited to a specific set of invited participants (Christiaanse 2005; Markus 2006; Steinfield et al. 2011). Shared hubs generally are structured as B2B electronic marketplaces, providing the ability to support vertical exchanges among supply chain participants, but incorporating competing companies and their partners as well. Such an arrangement is different from a private hub, which may or may not be standards-based, but is driven by a dominant player that only includes its own trading partners. This arrangement is often associated with *dedicated* supply chains, where a dominant manufacturer or retailer works with a specific set of suppliers who do not do business with other buyers. In many industries, however, supply chains are *interconnected*, such that a supplier does business with multiple buyers who compete with each other. A private hub managed by only one buyer would therefore only accommodate a portion of such a supplier's transactions, requiring additional investment in duplicate systems and processes to support exchanges with other trading partners (Steinfield et al. 2011).

The various combinations of IOS business functions, ownership and governance structures, and technological choices have implications for the extent to which IOS are adopted and implemented, as well as for the kinds of outcomes participants experience. For example, EDI-based IOS often lack participation by small- and medium-sized enterprises (SMEs) that face challenges implementing EDI due to a lack of requisite knowledge, limited resources, and fewer anticipated benefits due to their generally lower volume of transactions (Iacovou et al. 1995; Markus 2006; Segev et al. 1997). When forced to use EDI by larger and more powerful trading partners, SMEs may implement the system only superficially to satisfy partner requirements, which limits the overall integration and coordination benefits that such systems offer (Hart and Saunders 1997). Even the supposedly lower-cost web-based EDI approaches have not led to widespread EDI adoption by SMEs (Beck and Weitzel 2005). On the other hand, developing standards-based IOS and implementing these in shared coordination hubs can also be difficult because competing companies view the systems they use to exchange data with partners as strategic tools that convey competitive advantage, and are therefore prone to pursuing proprietary approaches (Clemons and Row 1988; Mukhopadhyay and Kekre 2002; Young et al. 1999). Additionally, vendors of IT products and services are also reluctant to develop standards-based systems for their clients, since this would presumably make it easier for their clients to switch to new vendors' products (Markus et al. 2006).

69.2 Impact on Practice

There are many well-established cases where companies initiating IOS connections with their trading partners have experienced such benefits as reduced costs of transactions, fewer errors with orders and delivery, greater efficiency due to the reduced need to rekey information into separate systems, and enhanced competitiveness. Examples include McKesson in the wholesale pharmaceutical supply industry (Clemons and Row 1988), Baxter in the medical supply industry (Short and Venkatraman 1992), Chrysler (Mukhopadhyay et al. 1995), Federal Express (Williams and Frolick 2001), Intel (Cartwright et al. 2005; Markus 2006), Japan Airlines (Chatfield and Bjorn-Andersen 1997), and Sabre in the airline reservation industry (Christiaanse and Venkatraman 2002).

Many of the cases cited earlier represent proprietary efforts implemented by a dominant trading partner for the purposes of improving its competitive position. One of the earliest and most heavily cited examples is the well-known case of McKesson's Economost system, introduced in the late 1970s and early 1980s. McKesson, a drug wholesaler, used its system to provide advanced electronic ordering and inventory management services to independent pharmacies that otherwise had little in the way of automated systems. Handheld terminals, communications lines, and a series of business applications were provided to client pharmacies. The system reduced transaction costs, improved inventory practices, solidified McKesson's role as the distributor for these drug retailers, and improved the ability of independent pharmacies to compete against national drugstore chains (Clemons and Row 1988).

The retail sector has also experimented with many IOS approaches, primarily aimed at reducing the proportion of inventory holdings that are *safety stock*—i.e., extra inventory held to protect a company from the negative effects of delayed shipments. Large retailers such as WalMart, as well as consumer products manufacturers like Proctor and Gamble, have experienced significant savings due to such IOS efforts as *vendor managed inventory* (VMI), *efficient consumer response* (ECR), and more recently, CPFR systems (Fliedner 2003). Essentially, these systems strive to support the sharing of retailers' *point-of-sale* (POS) data with partners further upstream in the retail channel, including wholesalers, manufacturers, and suppliers. POS data provides information about consumer demand, enabling each partner in the channel to adjust inventory stock based on real-time information, and speed up ordering and replenishment processes. Despite the efforts of the Voluntary Interindustry Commerce Solutions Association (VICS), an association of retailers and manufacturers, CPFR is not a fully standardized solution. Rather, it is largely limited to specific manufacturer–retailer chains where a strong participant drives implementation among its partners in the channel (Markus and Gelinas 2006).

Cartwright et al. (2005) detail the benefits that Intel has received due to its implementation of an IOS based on RosettaNet standards, enabling electronic connections with its many suppliers around the world. They report that by re-architecting its IT infrastructure around RosettaNet standards, Intel saved as much as $40 million in 2004 alone due to increased process automation and a greater ability to create value through outsourcing to third-party logistics providers. This case study also revealed an important benefit that follows from such an aggressive implementation of standards-based IOS—it supported greater integration of business processes across many disparate information systems *inside* the company. Nonetheless, many of the smaller business partners were unable to bear the costs of converting to RosettaNet standards, precluding Intel from mandating its use. This necessitated the maintenance of a range of information exchange options within Intel's supply chain, including RosettaNet, EDI, Internet-based file transfer protocol (FTP), and web-based transactions (Steinfield et al. 2011).

Industry-wide information system standards can help address the issue of the need to reinvest in duplicative IOS to do business with multiple trading partners, and can enable SME participation particularly when standards are designed around lower-cost Internet protocols such as XML and *service-oriented architectures* (SOA) (Boh et al. 2007; Löhe and Legner 2010; Steinfield et al. 2005; Venkatesh and Bala 2012; Wigand et al. 2005). SOA refers to a new approach to IOS that capitalizes on the Internet's wide reach by using standardized web-based services that work across applications (Löhe and Legner 2010). This allows organizations to have more easily reconfigurable IOS so that new connections and disconnections from trading partners can be more easily accommodated (Löhe and Legner 2010).

For example, XML-based standards for various transactions were developed in the home mortgage industry led by the Mortgage Bankers Association and its subsidiary, the Mortgage Industry Standards Maintenance Organization (MISMO). The availability of such industry-wide or *vertical information system* (VIS) standards has contributed to performance improvements over the industry as a whole, providing significant reductions in the total costs across the value chain for processing mortgage applications as well as the time from application to closing (Steinfield et al. 2005). Moreover, there is further evidence that MISMO standards have contributed to vertical disintegration in the mortgage industry, allowing companies to outsource various mortgage processing functions to SMEs as a result of the reduced coordination costs made possible by VIS (Wigand et al. 2005).

XML-based standards also figured heavily in RosettaNet, which not only helped to lower the costs and time for developing standards, but also enabled participation by the growing number of Asian suppliers to the electronics industry (Boh et al. 2007). More recently, Internet-based standards such as XML implemented into an SOA are forming the basis for inter-organizational business process standards (IBPS) (Venkatesh and Bala 2012). IBPS specify shared and agreed upon "interrelated, sequential tasks and business documents" to enable greater integration among business partners (Venkatesh and Bala 2012).

Not all IOS efforts have been successful. For example, Steinfield et al. (2011) review the history of problematic efforts by one automotive manufacturer to implement proprietary IOS throughout its supply chain. Automotive industry supply chains are characterized by multiple tiers of suppliers, and while there are extensive EDI linkages between top tier suppliers and manufacturers, IOS connections to lower tier suppliers are less common due to their lack of technical expertise and other resources. Moreover, many lower tier suppliers in the automotive industry do business with multiple manufacturers, making the supply chains interconnected rather than dedicated. Hence, it has been difficult to extend proprietary IOS throughout the supply chain. The lack of inter-operable IOS throughout the automotive supply chain imposes significant costs to the industry as a whole. A 2004 study by the National Institute of Standards and Technology (NIST), for example, found that inadequate use of IOS in the automotive supply chain costs the industry more than $5 billion due to errors, delayed shipments, and inadequate or excess inventory holdings (White et al. 2004). Despite the considerable cost savings that have been found to result from EDI use between automobile manufacturers and their suppliers (Mukhopadhyay et al. 1995), the lack of full implementation across the entire supply chain remains a consistent problem.

In summary, there are many well-known cases where use of IOS has contributed to lower costs, greater efficiency, increased business, competitive advantage, and broader performance benefits at the

industry level. However, IOS adoption is far from universal, and examples of failed implementations are also evident. Hence, research has investigated the factors associated with successful IOS development, adoption, and implementation, including the identification of both anticipated and unanticipated outcomes of use. An overview of research issues is provided in the following section.

69.3 Research Issues

IOS research can be broadly grouped into studies of IOS adoption, diffusion and implementation, IOS outcomes, and IOS development and governance. A common theme across much of the IOS research is that while the technical aspects of IOS—often called the information system artifact (Benbasat and Zmud 2003; Orlikowski and Iacono 2001)—are important, IOS should be viewed as *socio-technical systems* in order to understand how such systems are developed, adopted, implemented, and used and impact organizations and industries. That is, the social, organizational, and industry contexts in which IOS are embedded must be examined in concert with IOS technical features in order to understand the varying outcomes surrounding systems that contain seemingly equivalent technical features. Indeed, a recent meta-analysis of the EDI literature highlighted the inconsistent findings regarding factors influencing EDI adoption and benefits, positing such factors as industry influence and anticipated benefits as mediating forces that affect the relationship between hypothesized predictors of both adoption and benefit (Narayanan et al. 2009).

69.3.1 IOS Adoption and Implementation

Why do some organizations adopt IOS such as EDI, while others do not, despite the potential benefits they can obtain? Much of the past research has focused on EDI adoption, highlighting a number of antecedents that can be broadly grouped into internal and external factors. Internal factors found to influence adoption decisions include a variety of characteristics of the adopting organization that broadly reflect its *readiness* for IOS. These include having the requisite human, financial, and technical resources needed for implementation, compatible legacy systems, and business processes that have been improved to take advantage of IOS capabilities (Chau and Hui 2001; Iacovou et al. 1995; Markus and Christiaanse 2003; Narayanan et al. 2009; Premkumar and Ramamurthy 1995). External factors generally include aspects of the relationships between an adopting organization and its trading partners. Research has examined the extent of trust and the nature of dependencies among participants, whether there are power differences that might lead to coercion or other pressures to adopt, and the effect of incentives (e.g., promises of increased business) by a dominant partner as predictors of adoption (Chwelos et al. 2001; Hart 1998; Hart and Saunders 1997; Kumar and van Dissel 1996; Kumar et al. 1998; Riggins and Mukhopadhyay 1999; Teo et al. 2003).

As noted earlier, often EDI adoption by SMEs has historically been limited, which is not surprising as SMEs tend to have more limited financial resources, and can lack sufficient managerial and technical expertise needed to implement EDI. Hence, one research issue for IOS adoption researchers is how to increase adoption rates among SMEs. One approach is for the larger, more powerful trading partner to simply mandate adoption in order to do business with it; however, research has demonstrated that such attempts at coercion often do not succeed and generate resistance among smaller trading partners (Hart and Saunders 1997; Steinfield et al. 2011). SMEs may not refuse adoption altogether, but may adopt IOS technologies in a superficial manner, for example, for a limited set of transactions, depriving the partners of potential efficiencies or strategic benefits as a result (Massetti and Zmud 1996). To facilitate adoption, the IOS may be subsidized, or offered at no cost to smaller trading partners (Riggins and Mukhopadhyay 1999). Yet, even when entirely provided by the dominant partner, such systems still impose costs related to learning and the need to maintain redundant systems if the dependent partner does business with other organizations that use a different IOS. To insure that partners do engage in such *relationship-specific* investments, there must be sufficient expectation of future

business (Mukhopadhyay and Kekre 2002). Indeed, in one study of IOS use in four industries, electronic transactions with smaller suppliers of key inputs were more common in situations where there were quite strong ties—in some cases extending to ownership ties—between trading partners (Kraut et al. 1999). More broadly, the imposition of costs for adopting and implementing IOS has to be perceived as equitable, and the benefits have to be shared, in order to encourage greater adoption (Jap 1999).

69.3.2 IOS Outcomes

The outcomes of IOS adoption and use have also received a great deal of attention in the literature (Narayanan et al. 2009; Robey et al. 2008). In general, research has explored both tactical and strategic impacts of IOS use (Chatfield and Yetton 2000). Successful IOS use can result in many types of tactical benefits, ranging from reduced lead time for orders, faster deliveries, fewer errors in procurement transactions, fewer out-of-stock situations, reductions in the size of inventory holdings, increased staff efficiency, better monitoring of shipments, lower costs, and other transactional and operational benefits (Narayanan et al. 2009). Research on strategic benefits emphasizes competitive advantage outcomes such as growth in the volume of business with existing or new trading partners, improved relationships with trading partners leading to better communication and information sharing, improved market share, faster product design cycle times, and higher quality of products and services (Chatfield and Yetton 2000; Narayanan et al. 2009; Riggins and Mukhopadhyay 1994).

Not all implementations of IOS realize the benefits anticipated by their initiators, however. Research suggests that any benefits of IOS use, especially strategic ones, are mediated by the breadth and depth of adoption and the extent to which IOS use is integrated into an organization's business processes (Massetti and Zmud 1996; Narayanan et al. 2009). Massetti and Zmud (1996) identify four facets of EDI adoption, for example, that signify the intensity with which it has been integrated into business processes: (1) *volume* is overall extent to which a company's transactions are carried out over EDI, (2) *diversity* measures the range of different types of transactions handled by EDI, (3) *breadth* refers to the extent to which EDI is used with each of a company's trading partners, and (4) *depth* refers to the extent to which EDI has been integrated into the business processes of a company and a particular trading partner. Furthermore, business processes may need to be reengineered to take advantage of IOS capabilities, rather than simply automating existing processes in order to realize benefits (Clark and Stoddard 1996). JIT inventory practices can be enabled with IOS, but only if new business processes by suppliers and manufacturers are developed that support new channel distribution practices such as continuous replenishment. *Business process reengineering* can also help companies integrate across disparate legacy systems, such that enhanced internal efficiencies result from IOS use (Markus 2006).

In order to achieve high-value strategic benefits with more tightly coupled business processes over IOS, companies have to be willing to share proprietary information with each other. Because of the sensitive nature of the data that is shared, including design data, forecast data, operational data and more, there can be understandable reluctance to participate in such highly integrated IOS without a strong degree of trust between partners (Hart 1998; Hart and Saunders 1997). Hence, an ongoing thrust in the IOS research literature explores the nature of the relationships between IOS participants, and the influence of these relationships on outcomes of IOS use. Essentially, this research takes as a starting point that economic exchange can be facilitated by personal relationships among participants—trust and the social obligations that follow from being *embedded* in a network of relationships mitigate opportunistic behavior of participants and encourage reciprocation and cooperative exchange (Granovetter 1985; Kumar et al. 1998; Uzzi 1997). EDI researchers have further shown that when systems exhibit such embeddedness—fostering tight integration among trading partners characterized by high trust—the participants are more likely to experience the kinds of strategic benefits that yield competitive advantage (Chatfield and Yetton 2000).

These findings expose an interesting theoretical tension in IOS research, and reveal how IOS use can lead to impacts at higher levels of analysis such as on market structure, supply chains, and

whole industries. On the one hand, there is strong evidence inspired by transaction cost economic theory that increased use of IOS facilitates a "move to the market" encouraging companies to use networks to acquire needed inputs from the lowest cost suppliers that satisfy requirements (Alt and Klein 2011). This is occurring because IOS networks reduce the traditional transaction costs associated with market exchanges; they lower search costs and make it easier to monitor transactions (Malone et al. 1987). On the other hand, achieving strategic benefits seems to require tighter integration that is not consistent with arms-length, market transactions (Chatfield and Yetton 2000; Kraut et al. 1999). More research is needed to resolve this paradox, but one explanation may be that companies are more willing to use electronic market transactions for commodity inputs that are not highly *asset-specific* (i.e., they are not tailored to a particular company's needs). Conversely, they rely on tighter connections to a smaller set of suppliers for core inputs with greater asset specificity and a higher degree of proprietary information sharing. Such an arrangement with core suppliers reflects what has been called a "move to the middle" approach, representing a structure in between hierarchies and markets (Clemons et al. 1993).

Research on the impacts of IOS use at higher levels of analysis beyond the dyad is less common, despite several calls for more attention to the industry structure implications of IT-enabled inter-organizational exchanges (Gregor and Johnston 2001; Johnston and Gregor 2000; Segars and Grover 1995; Steinfield et al. 2005; Wigand et al. 2005). Segars and Grover (1995) studied the effects of IOS on three industries: (1) airlines and computer-based reservation systems, (2) the chemical industry's use of EDI, and (3) the pharmaceutical industry and EDI, finding structural influences such as greater consolidation in all three industries. The degree of structural change was a function of the ease with which competitors could imitate an IOS initiator's innovation; where easily imitated, IOS use proliferated rapidly throughout the industry. Johnston and Gregor (2000) develop a theory of industry-level impacts of IOS, emphasizing the need to look at higher-level factors such as the role of industry groups, government policy makers, and competitive dynamics in order to understand how IOS adoption and use occurs in different industries. These higher-level factors are also viewed as necessary for understanding how IOS use affects both routine business practices and the relationships among actors in the industry.

The availability and widespread acceptance of VIS standards is another important factor in understanding industry-level impacts of IOS. Due to the rise of lower-cost data-exchange protocols made possible by the growing use of Internet-based XML, many industries formed user-led associations with the purpose of establishing VIS standards (Markus et al. 2006). If successful, such efforts have the potential to include SMEs as participants in IOS for a number of reasons. First, if Internet- and XML-based, they can be less costly and less complex. Second, participating in systems built on open standards should presumably make it easier to connect with other trading partners, generating *network externalities* (benefits derived from the greater numbers of other users that are accessible in a network) that increase the attractiveness of using a standardized IOS (Zhu et al. 2006). In the home mortgage industry, for example, widespread usage of VIS standards resulted in significant industry performance benefits due to the aggregation of gains in efficiency among participating organizations (Steinfield et al. 2005). Structural changes in the mortgage industry were also observed, including evidence of consolidation among the larger players as well as growth in the number of smaller players who used VIS-based systems to fill specialty niches in the industry (Steinfield et al. 2005; Wigand et al. 2005).

69.3.3 IOS Development and Governance

Research on IOS development and governance can be vital to understanding the prospects for IOS adoption and use. IOS governance broadly refers to how decisions regarding IOS systems development and usage are made, and how individual and organizational action is coordinated vis-à-vis the IOS (Markus and Bui 2012). This can include decisions regarding who participates in the IOS, how any technical changes to the IOS or its configuration are determined, for what transactions the IOS will be used, and who owns any intellectual property rights associated with the IOS.

A recent focus of IOS development research has investigated the process through which industry consortia develop VIS standards (Boh et al. 2007; Markus et al. 2006). Markus et al. (2006) conceptualize this process as a *collective action* problem. Such problems refer to situations where a group effort is required to achieve a collective good, but such goods have the characteristics of *public goods*, where *free riding* can occur. That is, participants who have not necessarily contributed to the production of the good can still enjoy its benefits, and therefore may have a disincentive to help shoulder the associated costs of production. VIS standards are public goods; organizations do not have to contribute to their development, but nonetheless benefit from their existence if they achieve widespread adoption. Markus et al. (2006) highlight the types of collective action dilemmas that need to be resolved in order for industry consortia to be able to effectively develop standards that have a greater probability of achieving widespread adoption. They point out that standards development and standards diffusion are two linked collective action problems, and it is possible to solve the former in such a way that the latter is less likely. For example, if the consortia privilege only certain types of participants (e.g., large companies, or those from only one segment of an industry) and not others, then there is a greater chance that whatever standard is developed will not adequately address the needs of those who did not participate in the standards development process. This can lead to an industry standard that is not taken up by the underrepresented companies, and hence fails to achieve widespread adoption, depriving all industry participants of potential benefits. Their case study of the home mortgage industry identifies the diverse interests of different types of industry stakeholders—and particularly emphasizes the different needs of IT vendors versus IOS users. Bringing IT vendors into the process, even in user-driven consortia, is essential so that the software solutions available to industry participants will be standards-based. This is especially important for SMEs that are not likely to develop their own IOS. Hence, involvement in the development of the standard by all segments of the industry was a crucial strategy undertaken by MISMO in order to ensure that the outcome was palatable across the key stakeholder groups.

A variety of governance issues come to the fore when IOS standards are examined in this light. For example, standards consortia must deal a priori with intellectual property issues, so that when a standard is developed, adopting companies are not obligated to pay unexpected licensing fees or royalties to participants who had not revealed ownership or granted royalty free use of patents that were used (Steinfield et al. 2007). Processes for ensuring compliance with standards must be in place to avoid the problem of *fragmentation* of the standard, which can occur when there is some leeway in implementing the standard and individual vendors and other organizations make small changes that cause one version of the IOS to be incompatible with another (Damsgaard and Truex 2000). Other direct governance issues related to the function of standards consortia include rules for who can participate in the work of the committees developing the standards, as well as voting rules for selection of officers and for making other decisions (Markus et al. 2003). All of these factors can shape the development process in ways that not only influence IOS standards development, but also the prospects for diffusion throughout the industry. Standards that are largely driven by dominant companies and which fail to take into account the needs of other industry participants are less likely to experience successful diffusion.

Not all governance issues are about standards development. As noted earlier, some IOS are hub-based, and interconnect many different trading partners in a common system. A recent study by Markus and Bui (2012) identifies the governance challenges faced by what they call *inter-organizational coordination hubs* (ICHs). ICHs face such challenges as attracting adequate investment, ensuring participation, and determining rules related to ownership and access to the data they generate (Markus and Bui 2012). In one study of an ICH developed for an automotive supply chain, the participants opted for a third-party owned IOS to avoid perceptions that the system would only cater to the needs of the dominant manufacturer who functioned as the buyer in the supply chain (Steinfield et al. 2011). Moreover, they encouraged participation by allocating costs for the system according to the extent to which participants benefited from its use; in this case since the buyers benefited the most, they absorbed the lion's share of the costs.

69.3.4 Toward a Research Agenda

The previous sections have highlighted a number of significant research questions related to IOS adoption and implementation, IOS outcomes, and IOS development and governance, and offer insights into the key directions for research on IOS in the next several years. In the area of IOS adoption and implementation, there is clearly a need for more research that clarifies how organizations, and particularly SMEs, evaluate the risks and rewards of participating in an IOS. How can industry associations help to diffuse the IOS standards they have developed more effectively, and encourage companies in their industry to adopt them? What approaches can companies take to increase trust and convince smaller trading partners to sign on to use IOS?

In the area of IOS outcomes, more research is needed to better understand why some IOS participants benefit while others do not. What IOS arrangements best contribute to improved outcomes for all participants? How can IOS be structured so that there is not only a reliance on standards to keep costs down, but also ample opportunity for companies to employ IOS strategically in ways that are difficult for competitors to imitate?

IOS development and governance research in the coming years will be critical for understanding the questions posed earlier. For example, research on how to attract more SMEs to participate in VIS standards making will be essential for solving diffusion and adoption problems. With more representative participation, there should be a better match between SME needs and the types of standards that are developed. Moreover, awareness of the availability and utility of standards should be greater and SME involvement in the process may motivate later adoption and use. Research on governance of IOS will be essential as well. With the growth of shared coordination hubs, more research is needed to understand if such shared IOS platforms based on open standards are more likely to find acceptance, or if companies will resist due to perceptions of a loss of control and competitive advantage? Clearly, much work remains to be done over the coming years to provide guidance to IS managers and to IT vendors so that the potential benefits of IOS can be more effectively harnessed.

69.4 Summary

This chapter has provided a broad introduction to the field of IOS. Modern organizations of all types—public and private, profit and nonprofit, large and small—need to rely on IOS to reduce costs, improve quality of products and services, and compete effectively. Implementing IOS, however, is not an independent decision of a single organization, and requires cooperation among the participants in order to achieve desired outcomes.

An overview of the many different types of IOS was provided, ranging from dyadic systems that link a pair of organizations for computer-based transactions to ICHs that can interconnect and support transactions among a supply chain or even an entire industry. Further distinctions between proprietary versus standards-based IOS were described.

The successful use of IOS has had significant impacts in many industries, and is associated with such far-reaching innovations as JIT inventory management practices and the advent of computerized reservation systems. However, success is not guaranteed, and there are many instances where organizations have attempted to implement IOS only to find that partners resist adoption or adopt in ways that limit overall benefits to the various stakeholders. SME adoption of IOS technologies such as EDI in particular has been problematic.

As detailed in this chapter, research has investigated the factors that influence IOS adoption and use, as well as the outcomes that organizations experience from their use of IOS. Such factors as having requisite technical competence, financial resources, and experience with existing internal systems reflect a readiness for IOS that can enhance prospects for adoption. In addition, the review has revealed the importance of trust among IOS participants, anticipated benefits, and the role of incentives in spurring IOS adoption. The research on IOS outcomes detailed in this chapter identifies two broad types of

benefits that participants can experience with successful use of IOS: operational benefits that largely result from the ability to engage in more efficient transactions and strategic benefits related to IOS users' relationships with their partners and users' competitive positions in their industry. IOS impacts can be far-reaching, and research has also identified ways in which IOS use can influence entire industries by improving performance and altering the industry structure.

Finally, the study of IOS development and governance was introduced as an important area of research. Questions such as how and why some industries have been able to successfully develop industry-wide IOS standards while other others have failed represent new areas of research that have significant societal and economic implications. As reliance on IOS becomes ever more pervasive, research is needed to more fully understand and solve the governance challenges raised by emerging IOS configurations such as shared coordination hubs. Advances in technology are creating many new opportunities, but the benefits can only be realized when the business and organizational context of IOS use is taken into account.

Glossary

Asset specificity: When goods or services in a transaction are of value only to a particular recipient and cannot be sold as is to other potential buyers, they are considered highly specific assets. In general, when needed inputs exhibit strong asset specificity, transaction cost theory suggests that organizations will seek to produce in-house (i.e., use hierarchy as governance) to protect themselves from threats of opportunism.

Bullwhip effect: Bullwhip effects occur when variations in orders propagate up the supply chain as each company builds in its own buffer inventory under conditions of uncertainty about actual demand, yielding larger and larger variations from actual sales data the further one goes up the chain.

Business process reengineering: The process of redesigning work flows to improve business performance, often motivated by the desire to take advantage of new capabilities made possible by new information systems.

Collaborative Planning, Forecasting, and Replenishment (CPFR): A set of guidelines promoted by the Voluntary Interindustry Commerce Standards (VICS) Association to facilitate the cooperative management of inventory by sharing data on customer demand as well as production and distribution across a supply chain.

Collective action: The set of behaviors by a group of individuals or organizations as they work to achieve a common goal or objective.

Efficient consumer response (ECR): An approach to achieving more timely inventory practices by linking replenishment to actual consumer demand rather than by having retailers make orders based on periodic forecasts.

Electronic data (or document) interchange (EDI): The structured transmission of computerized messages between organizations to support the electronic exchange of standard business documents such as purchase orders or bills of lading. EDI message standards have been developed globally by the International Standards Organization (ISO), as well as by national standards bodies and many different industry associations.

Electronic hierarchy: A type of relationship between two organizations that are connected by an IOS where the two company's business processes are tightly integrated and governed by management control as opposed to market forces.

Electronic market: A form of electronic interconnection among groups of organizations where the actions of the participants are controlled by market forces, enabling companies to engage in transactions with a number of different partners due to the reduced costs of coordination afforded by computer-based networks.

Free riding: Allowing others to bear the costs of producing a collective good while enjoying the benefits of the good.

Governance: In the context of an IOS, governance refers to how decisions regarding IOS systems development and usage are made, and how individual and organizational action is coordinated.

Interconnected versus dedicated supply chains: Interconnected supply chains are those in which suppliers provide goods and services to multiple buyers, while in dedicated supply chains, a supplier typically only sells its output to a single buyer.

Just-in-time (JIT) inventory practices: An inventory management approach that minimizes inventory holding costs making more frequent deliveries of supplies as close as possible to the time when they are needed based on real-time information about stock levels.

Network externality: A benefit from using a good or service that is a function of the number of others that are also using the same good or service, and which is not necessarily captured in the price. An example is the benefit of having more potential trading partners in an IOS that has a larger number of participants, even though each user does not pay more when a new participant joins.

Public good: Such goods are types of goods that have the attributes of being *non-rivalrous* and *non-excludable*. Non-rivalrous means that one person's (or organization's) use of the good does not diminish its supply or prevent others from using it. Non-excludable means that it is not possible to prevent others from using the good once it is produced. A public/open IOS standard is often thought of as a public good, since those who did not contribute to its development can still use it.

Service-oriented architecture (SOA): An emerging approach to information system design utilizing web services accessible through the Internet that makes it easier to reuse software components across applications. Such architectures make IOS more dynamic and reconfigurable.

Supply chain visibility: Supply chain visibility refers to the ability to track goods and related supply chain events from the point of production to the delivery at the end-user's premises.

Vertical information system (VIS) standards: These are a set of data definitions and electronic transaction standards that are focused on the unique needs, products, and services relevant to the value chain of a specific industry. VIS standards have been developed in many industries such as the mortgage industry, insurance industry, automotive industry, and so forth.

70.1 Introduction

Organizations continue to make substantial investments in information systems (IS), expecting positive impact on the organization and its employees. Such investments in contemporary information systems are under increasing scrutiny, and there is strong pressure to justify their value and contribution to productivity, quality, and competitiveness of organizations (Markus et al. 2003), regardless of the state of the economy (Kanaracus 2008). Even though it is difficult, research has also emphasized the importance of systematically measuring information system success. As stated by Peter Drucker (1987), "If you cannot measure it—you cannot manage it" (p. 47). With contemporary organization-wide IS, measuring success takes on special importance since the costs and risks of these large technology investments rival their potential payoffs.

In practice, however, IS investments, though often carefully rationalized in advance, are seldom systematically evaluated after their implementation (Thatcher and Oliver 2001). When post-implementation reviews do occur, their process and measures are often idiosyncratic and lacking credibility or comparability. Moreover, the impacts of information technology (IT) are often indirect and influenced by factors related to the user, organization, and environment; therefore, measurement of information systems success is both complex and illusive. In academic research, however, there is a long-standing tradition of research on system evaluation, dating to 1970s (King and Rodriguez 1978; Rolefson 1978; Matlin 1979). In 1992, DeLone and McLean published their IS success model, which is one of the most widely cited papers of IS success. Moreover, approaches like the Balanced Scorecard also have received great

attention over the years. Yet, as Sabherwal et al. (2006, p. 1849) observe, "Despite considerable empirical research, results on the relationships among constructs related to information systems success, as well as the determinants of IS Success, are often inconsistent." In order for the IS success research to be relevant to practitioners and to continue as a vibrant research stream for academia, we must continue to identify opportunities and challenges for future researchers.

The objective of this chapter is to revisit the foundations of system evaluation studies and to identify some opportunities for future studies. In order to identify the opportunities, we make specific observations on five fundamental questions of system evaluations. Taking the DeLone and McLean IS success model as a framework, this chapter will make several recommendations regarding the challenges and opportunities that we must pursue. Our recommendations herein, though based on the DeLone and McLean model, can be generalized to most IS performance measurement approaches.

The opportunities and challenges of IS success research are derived using six simple considerations. As simple as they might sound, these six considerations provide an organized way to focus on the measurement properties of information system success. Our aim in this chapter is not to criticize the DeLone and McLean model. On the contrary, our discussion herein is motivated by the opportunities that have always existed with their framework. We explore what it would take to extend their model into new directions.

70.2 Information Systems Success

Keen (1987, p. 3) described the mission of IS as "the effective design, delivery, use and impact of information technologies in organizations and society." Based on this view of information systems, we believe the evaluation of the "effectiveness" or "success" of information systems is an important aspect of the information systems field, both in research and in practice. However, with the evolution of systems, users, and user requirements, the manner in which we evaluate the success of an information system has changed over time as the context, purpose, and impact of information systems have evolved. It is, therefore, essential to understand what these changes have been and what they mean for the future.

In general, information systems success research evaluates the effective creation, distribution, and use of information via technology. As information systems have developed since the mid-1950s, information has become more voluminous and systems have become ubiquitous and accessible by all. If we believe that information is power, this progress in information availability has changed the power relationships between corporations and consumers, between buyers and suppliers, between small business and large business, and between citizens and their governments.

However, unlike single, one-off investments, information systems are long-term investments, whose performance is subjected to a range of contextual factors. Moreover, IS, being long-term investments, are expected to yield a continuing flow of benefits into the future (Gable et al. 2008). Gable et al. (2008) defined IS success as a measure at a point in time of a stream of net benefits from the IS, to date and anticipated, as perceived by all key user groups. Further complexity arises due to changes in the user base and the access mechanisms, making infinite possibilities in terms of the purpose of an IS and the definition of its stakeholders.

Historically, researchers have employed objective, financial indicators to assess the impact of an information system (e.g., Brynjolfsson and Hitt 1996). However, as many have argued (Davenport 2000; Kaplan and Norton 2000), contemporary information systems provide financially quantifiable benefits as well as substantial nonfinancial benefits. Considering this, to measure the success of these various information systems, organizations are moving beyond traditional financial measures, such as return on investment and return on assets (Rubin 2004). For example, research suggests that large enterprise systems provide tangible as well as substantial intangible benefits to organizations, and highlight the importance of capturing these intangible benefits. In an effort to better understand such benefits of their IS, organizations have turned to methods such as the Balanced Scorecard of Kaplan and Norton (1996). Researchers, too, have developed several

methods for assessing IS success using intangible measures (DeLone and McLean 1992, 2003; Gable et al. 2008), most focusing on the subjective assessment of the system by the users of the system. Of these subjective, user-centric system evaluations, the DeLone and McLean (1992) IS success model, in particular, has been widely adopted in a number of research contexts. The DeLone and McLean IS success model has been widely adapted and tested in a number of different system types (e.g., e-commerce, knowledge management systems, ERP) and has been validated across range of geographical settings.

70.3 DeLone and McLean IS Success Model

This chapter will later briefly introduce the DeLone and McLean model since it is the most widely cited and used IS evaluation model in academia. As of September 2012, we found over 8000 citations in Google Scholar for their 1992 (~5000 citations) and 2003 (~3000 citations) papers. We will summarize here its evolution, strengths, potential weakness, and limitations. The DeLone and McLean model is a good example of how the IS success construct has evolved over the years.

Early attempts to define information system success were ill-defined due to the complex, interdependent, and multidimensional nature of IS success. To address this problem, DeLone and McLean (1992) performed a review of the research published during the period 1981–1987, and created a taxonomy of IS success based upon this review. In their 1992 paper, they identified six variables or components of IS success: system quality, information quality, use, user satisfaction, individual impact, and organizational impact. However, these six variables are not independent success measures, but are interdependent variables. Figure 70.1 shows this original IS success model (DeLone and McLean 1992). Figure 70.2 shows the revised model in 2003, where the authors added service quality and consolidated organization and individual impacts to net benefits.

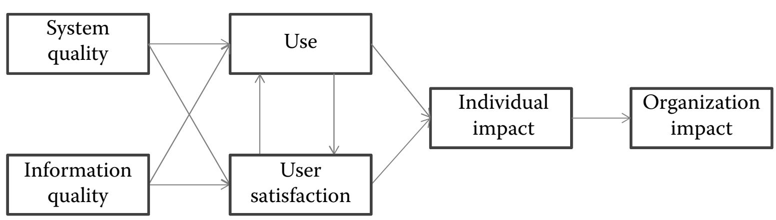

FIGURE 70.1 DeLone and McLean (1992) IS success model.

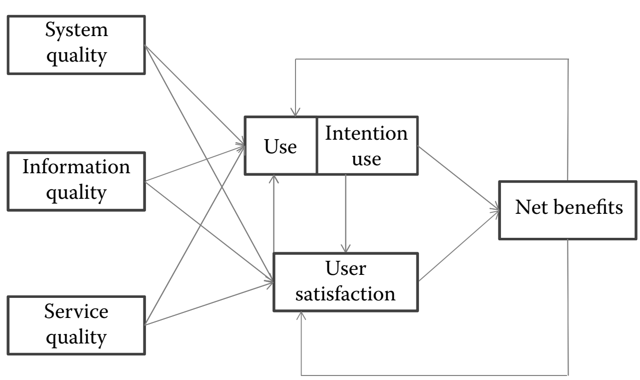

FIGURE 70.2 Revised DeLone and McLean (2003) IS success model.

As the authors explain (DeLone and McLean 2003, pp. 10–11):

> The primary purpose of the 1992 article in Information Systems Research was to synthesize previous research involving MIS success into a more coherent body of knowledge and to provide guidance to future researchers. … The semantic level is the success of the information in conveying the intended meaning. The effectiveness level is the effect of the information on the receiver. In the IS Success Model, SYSTEMS QUALITY measures technical success; INFORMATION QUALITY measures semantic success; and USE, USER SATISFACTION, INDIVIDUAL IMPACTS, and ORGANIZATIONAL IMPACTS measure effectiveness success.
>
> Based on both process and causal considerations, these six dimensions of success are proposed to be interrelated rather than independent. … A temporal, process model suggests that an information system is first created, containing various features, which can be characterized as exhibiting various degrees of system and information quality. Next, users and managers experience these features by using the system and are either satisfied or dissatisfied with the system and/or its information products. The use of the system and its information products then impacts or influences the individual user in the conduct of his or her work, and these individual impacts collectively result in organizational impacts.

The primary conclusions of DeLone and McLean's 1992 paper (1992, pp. 87–88) were quoting the original:

- "The multidimensional and interdependent nature of IS success requires careful attention to the definition and measurement of each aspect of this dependent variable. It is important to measure the possible interactions among the success dimensions in order to isolate the effect of various independent variables with one or more of these dependent success dimensions. Selection of success dimensions and measures should be contingent on the objectives and context of the empirical investigation; but, where possible, tested and proven measures should be used."
- "Despite the multidimensional and contingent nature of IS success, an attempt should be made to reduce significantly the number of different measures used to measure IS success so that research results can be compared and findings validated. More field-study research should investigate and incorporate organizational impact measures."
- "This success model clearly needs further development and validation before it could serve as a basis for the selection of appropriate IS measures."

70.3.1 Model Adoption

Shortly after the publication of the original DeLone and McLean success model, IS researchers began proposing modifications to this model. Accepting the authors' call for "further development and validation," Seddon and Kiew (1996) studied a portion of the IS success model (i.e., system quality, information quality, use, and user satisfaction). In their evaluation, they modified the construct, use, because they "conjectured that the underlying success construct that researchers have been trying to tap is Usefulness, not Use" (p. 93). Seddon and Kiew's concept of *usefulness* is equivalent to the idea of *perceived usefulness* in technology acceptance model (TAM) by Davis (1989). They argued that for voluntary systems use is an appropriate measure; however, if system use is mandatory, usefulness is a better measure of IS success than use. DeLone and McLean (2003) responded that even in mandatory systems, there can still be considerable variability of use and therefore the variable use deserves to be retained.

Researchers' adoption of the IS success model has been overwhelming. Many of these authors' articles positioned the measurement and/or the development of their dependent variable(s) within the context of the DeLone and McLean IS success framework. By using the model as a common framework for reporting and comparing research work involving IS success or effectiveness, we believe one of the primary purposes of the original article has been achieved.

Although many of the cited articles tend to justify their empirical measurement of IS success by citing the DeLone and McLean IS success model, some of them fail to heed DeLone and McLean's cautions. They state "… they [researchers] used the model like a drunkard uses a lamppost—for support rather than for illumination. They overlooked the main conclusion of the article—that IS success is a multidimensional and interdependent construct—and that it is therefore necessary to study the interrelationships among, or to control for, those dimensions, … Researchers should systematically combine individual measures from the IS success categories to create a comprehensive measurement instrument" (1992, pp. 87–88). Although many authors did not choose to measure (or control for) the various dimensions of IS success, a number of other researchers have used multidimensional measures of IS success in their empirical studies and have analyzed the interrelationships among them.

The DeLone and McLean (1992) IS success model has weathered criticism, as well as received widespread acknowledgement as one of the watershed studies in the IS discipline. Their model has been tested in full, and in some cases partially, in over 200 studies since 1992. In 2008, Petter et al. (2008) identified 180 empirical studies that had employed the DeLone and McLean success model. The model has been applied in system evaluation studies, data processing systems, e-business applications, and Enterprise Resource Planning systems. As Petter et al. (2008, p. 237) noted "… As a field, we have made substantial strides towards understanding the nature of IS success. For example, the widely cited DeLone and McLean model of IS success (1992) was updated a decade later based on a review of the empirical and conceptual literature on IS success that was published during this period (DeLone and McLean, 2003) …. [S]ome researchers have synthesized the literature by examining one or more of the relationships in the DeLone and McLean IS success model using the quantitative technique of meta-analysis (Mahmood et al. 2001; Bokhari 2005; Sabherwal et al. 2006) to develop a better understanding of success. Others have started to develop standardized measures that can be used to evaluate the various dimensions of IS success as specified by DeLone and McLean" (e.g., Sedera and Gable 2004).

70.4 Identifying Opportunities in IS Success

Having discussed IS success, the DeLone and McLean IS success model, and some criticisms of it, we will now address some potential opportunities and challenges for future IS success research. Our discussion here is guided by Cameron and Whetten (1983), who suggested five fundamental questions that must be considered in any evaluation. Next, we focus on the opportunities specific to the DeLone and McLean model.

As Cameron and Whetten (1983) suggest, five fundamental questions must be answered before attempting any evaluation of success:

1. WHAT SYSTEM?—On what domain of activity (what system) is the assessment focused?
2. WHO?—From whose perspective is effectiveness being assessed?
3. WHY?—What is the purpose for assessing effectiveness?
4. WHEN?—What time frame is being employed?
5. HOW?—What measures and constructs are being used?

We believe that the evaluator must address the aforementioned questions before embarking on an evaluation. The following section discusses each of those five questions in relation to information system success.

70.4.1 WHAT? The "System" of Evaluation

In defining a "system," there are two points of view to be considered: (i) the type of the system and (ii) the scope of the system. First, in every IS success study, one must specify the *type* of the system or application that they are evaluating and develop approaches and measures appropriate to them. Second, and in most cases concurrently, you must select the *scope* of the system/application.

First, studies on system typologies identify the salient differences between *different types of systems*. For example, McAfee (2006) identifies three types of systems: functional IT, network IT, and enterprise IT. He notes that there are substantial differences among these three in terms of their core purpose, the types of users (i.e., the potential study participants), and the system outcomes. Thus, an IS success study must derive it objectives, approach, and measures according to the types of the IS.

Second, one must establish a clear scope of the system to be evaluated. For example, a system can be defined as narrowly as a particular process, module, or function (e.g., a procurement process) or as broadly as an application portfolio. In each case, noting that neither approach is superior or inferior, the researcher must consider the implications of the scope of the system under investigation. Both system types and scope of the system provide useful boundaries for a system evaluation. Thus, akin to arguments by Burton-Jones and Straub (2006), one must select appropriate measures for the circumstances, without employing "omnibus" measures. The following section provides a summary of McAfee's classification of systems and its implications for IS success studies. Next, we focus on the scope of the system and how it influences IS success studies.

70.4.1.1 Types of Information Systems

At a high level, information systems can be classified as (i) hedonic—developed for pleasure and enjoyment or (ii) utilitarian—developed to improve individual and organizational performance (van der Heijden 2000). However, hedonic applications in organizations are still not common. Thus, in this discussion, we adopt the utilitarian subclassifications of McAfee (2006). Table 70.1 provides a summary of system types, examples, and considerations for system success.

TABLE 70.1 System Classifications and Implications for IS Success

Category	Function IT	Network IT	Enterprise IT
Definition	Assists with the execution of discrete tasks	Facilitates interactions without specifying their parameters	IT that specifies business processes
Characteristics	Can be adopted without complements[a] Impact increases when complements are in place	Does not impose complements,[a] but lets them merge over time Does not specify tasks or sequences Accepts data in many formats Use is optional	Imposes complements[b] throughout the organization. Defines tasks and sequences Mandates data formats Use is mandatory
Examples	Spreadsheets, computer-aided design, statistical software	E-mails, instant messaging, wikis, blogs, and mash-ups	ERP, CRM, and SCM
Automation	Some degree of automation (e.g., spell check)	Very low level of automation	High level of automation
Key user groups	More likely to have a single key user group	More likely to have a single key user group	Multiple key user group using the same system very differently
Considerations for system success	Most users would remain proficient with the basic system features Potential to improve performance through deeper and exploratory use	Limited work-oriented functionality Access to system features is equal across all key user groups Depth of use would not result in substantial improvements	High automation of business processes Many key user groups have different types of uses Must consider mandatory and nonmandatory uses For processes with high automation, frequency of use will only provide observations of efficiency

[a] Complements are defined by McAfee (2006, p. 142) as "*organizational innovations, or changes in the way companies get work done*."

[b] Examples of complements that allow working performing technologies, according to McAfee (2006, p. 143) are "*better-skilled workers*," "*higher levels of teamwork*," "*redesigned processes*," and "*new decision rights*."

The characteristics of each system type are explained in Table 70.1. We acknowledge there are other classifications of system types, but we chose McAfee's classification for its simplicity, yet for its discussion of key user groups and system complexity for success measure specifications.

McAfee's (2006) classification of systems highlights the danger in using all-purpose, omnibus constructs and measures for IS success evaluations. The characteristics of the three types of systems show that each system is designed to provide specific, almost nonoverlapping service to a specified group of key users.

70.4.1.2 Scope of the System under Investigation

The second consideration relates to scope of the system. This is more complex than system classifications and can yield multiple overlapping interpretations. With the ever-expanding boundaries of systems, information systems are no longer restricted to "back-office" applications. More and more organizations now use organizational-wide systems (like ERPs), some consumed through web portals, hosted in the "cloud," and managed by third-party service providers.

Thus, defining the "scope" of a system is an important consideration in IS evaluation. The focus will depend on the areas that are generally defined as "the system." For example, Seddon et al. (1999, p. 6) identified six levels of scope that should be evaluated:

1. An aspect of IT use (e.g., a single algorithm or form of user interface)
2. A single IT application (e.g., a spreadsheet, a PC, or a library cataloging system)
3. A type of IT or IT application (e.g., TCP/IP, a GDSS, a TPS, a data warehouse, etc.)
4. All IT applications used by an organization or sub-organization
5. An aspect of a system development methodology
6. The IT function of an organization or sub-organization

As suggested in Seddon et al. (1999), isolating "the system" for evaluation is difficult, but must be done for evaluations to be meaningful. Even after scoping the boundaries of the system being considered for evaluation, certain aspects would still need to be resolved in the minds of both the evaluators and the researchers. They include other systems or portfolio of systems, the infrastructure, the IT function or the IT support service quality, and the administrative area with which the system is most closely associated.

A key challenge for the researcher here is to gain an understanding of the system of interest, without being influenced by aspects that may be a part of the system, but not be a part of the system of interest. As noted in several recent studies (DeLone and McLean 2003; Gable et al. 2008; Petter et al. 2008), most past studies reuse measures and constructs without much considerations as to the type and scope of the system(s). Therefore, this presents a clear opportunity for IS researchers to identify ways to determine the scope of a system. For example, a generalizable taxonomy to identify the system of interest may provide much value for the cumulative tradition of IS success research. The relationship between scope of IS and the type of IS is depicted in Figure 70.3.

Some considerations for developing such a taxonomy are stated here. First, the perceptions of the quality of the system may be influenced by perceptions of the infrastructure; a system may be perceived as slow, because the associated infrastructure is inadequate or underpowered. However, in such circumstances evaluators may not be knowledgeable or aware of the circumstances beyond their immediate work systems, and would not recognize the issues attributable to the IT infrastructure rather than to the system of interest. Second, the scope of the system being evaluated can be defined more narrowly or more broadly, depending on the nature of the evaluation being undertaken. This would make it impossible to compare and benchmark across systems. Third, increasingly when systems services are delivered using web portals, researchers would find it difficult to identify "the system." Similarly, end users will find it even more difficult to identify which system they are accessing and how they will receive information from it. If the researcher evaluates the goodness of the web portal at a high level, such information would not be adequate to address the management and performance issues of the underlying system.

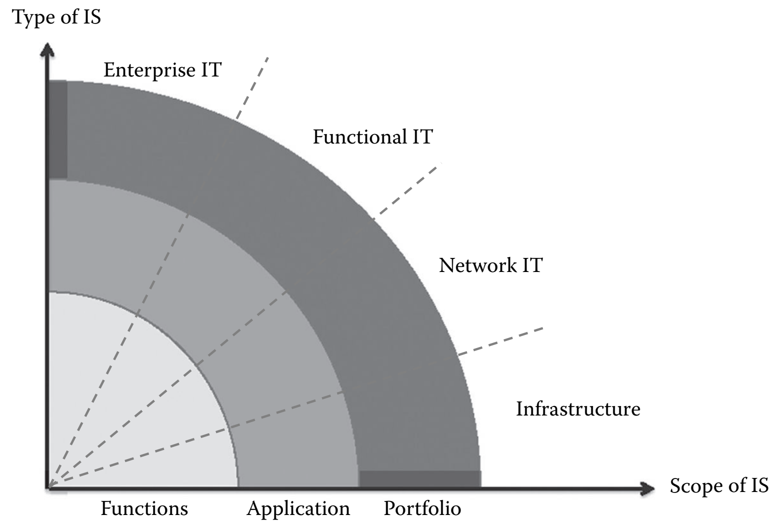

FIGURE 70.3 Selecting the scope of IS success.

70.4.2 WHO? The Stakeholders

The stakeholder is the one who interacts with the system and consumes the information generated by the system. Stockdale and Standing (2006) argue that "… the evaluators must decide which groups are relevant to the project being evaluated. The power associated with stakeholder groups and its implications for effective evaluation is a complex issue that the evaluators should be aware of since there is a danger that outcomes may be skewed to meet the objectives of those holding power" (p. 1093). Stockdale and Standing (2006) identify four types of stakeholder groups relevant for a system evaluation:

1. Initiators of the evaluation
2. The evaluators who conduct the evaluation
3. The users of the systems being evaluated
4. A range of other parties such as trade unions and government agencies

In relation to the Stockdale and Standing (2006) stakeholders, most of the IS success studies have included the users of a system. Seddon et al. (1999, p. 167) also introduced a classification of stakeholders and found that the evaluation of IS effectiveness was generally based on the perceptions of one or more of the following five types of stakeholders:

1. An independent observer, who has no personal stake in the measure
2. An individual user, who evaluates a system from his or her own point of view
3. A group of users, e.g., a group decision support system (GDSS)
4. The management or owners of the organization
5. A country or all of mankind

Here too, many of the IS success studies appear to have concentrated on the post-implementation evaluation of system success, employing the perceptions of the end users. With the transition from in-house, custom-made, stand-alone legacy IS applications to integrated, customizable, and packaged applications, organizations are looking to engage multiple user groups with a single application. For example, Grover et al. (1996) state that there are four key user groups that could take part in a contemporary IS success data collection. The four groups are operational, management, strategic, and technical staff. Similar views have been reported by other researchers as well (Kang and Santhanam 2003;

Grabski et al. 2011). For example, in enterprise systems (e.g., SAP), the operational staff would use an ES for routine business transactions on a daily basis, while middle management would periodically engage the same system for management decision making. This ability to serve multiple key user groups with a single system has provided organizations with great potential in the standardization of information, process automation, and improvements of transparency (Morris and Venkatesh 2010; Seddon et al. 2010; Strong and Volkoff 2010).

How do the multiple stakeholders of a system impact information system success? First, different stakeholders may have different opinions regarding the performance of the same system. As Gable et al. (2008) have demonstrated, different stakeholder groups will have different views of the DeLone and McLean success dimensions. Gable et al. (2008) observed that operational staff tend to place a higher emphasis on system quality when they evaluate information system success, while senior executives (e.g., strategic-level staff) place a higher emphasis on organizational benefits. Second, Gable et al. (2008) stressed the importance of canvassing all stakeholders of a system. They argue that unless all users are canvassed for their views of a system the evaluation will only be partial.

The differences in perspectives across information system stakeholders have been long established in the information system success literature (Cameron and Whetten 1983; DeLone and McLean 1992; Seddon et al. 1999). However, information system research is yet to fully appreciate the impacts of using a single system by multiple user groups. For instance, these different user groups often have multiple and often conflicting objectives and priorities (Gable et al. 2008; Strong and Volkoff 2010). For instance, one user group could have one experience in their interactions with a system, as compared to the interactions of another user group using the same system (Park et al. 2007). Although an enterprise system may be viewed as a success from the standpoint of one user group, it may be interpreted as unsuccessful by another (Urbach et al. 2009).

Robert Anthony (1965) provides a useful classification scheme of management-level activities: strategic, managerial, and operational. The different levels presented by Anthony are important in IS evaluation studies. According to Anthony, the strategic level focuses on organization-wide objectives and allocates the necessary resources to achieve these objectives. The strategic level is involved in complex, irregular decision making, focusing on providing policies to govern the entire organization. At the strategic level, information requirements are ad hoc in nature, with information relevant for long-term organizational planning. At the managerial level, the information requirements are focused on ensuring that the resources, both human and financial, are used effectively and efficiently to accomplish the goals stated at the strategic level. The characteristics of the information required at the managerial level are different from those that are required at the strategic level. The managerial level deals with integrated and procedural information that is necessary for a precise task. Therefore, managers at this level tend to prefer "goal congruent" information systems. At the operational level, employees are involved in highly structured and specific tasks that are structured, routine, and transactional. Tasks carried out at the operational level are precise and are governed by organizational rules and procedures. Operational employees deal with real-time data focused on individual events with little or no emphasis on key organizational performance indicators. The three levels of management described by Anthony tend to be hierarchical on several dimensions: (1) the time horizon of decisions (i.e., long, medium, and short term), (2) the importance of a single action (i.e., critical, important, and routine), and (3) the level of judgment (i.e., strong, moderate, and modest). Using Anthony's framework, Table 70.2 demonstrates possible differences in opinions of the three management levels in relation to enterprise system and information requirements.

Alloway and Quillard (1983) emphasize the importance of operational personnel using a system appropriately in order for the senior managers to be able to make effective use of the system, since the aggregated information at the managerial level depends on the transactions at the operational level. Furthermore, it is argued that enterprise systems, in particular, often fail at the operational and transactional levels because operational users take shortcuts to circumvent the restrictive standards of the enterprise system (Mabert et al. 2001; Umble et al. 2002; Sedera et al. 2003).

TABLE 70.2 Key-User-Group Characteristics

		End-User Cohorts		
	Perspective	Strategic	Managerial	Operational
System	System use	Less direct access	Sporadic, ad hoc	Daily, routine access
	Use of system features	Rare use of high-level reports	Aggregated, summative	Transactions
	Level of interaction	Generally minimal	Moderate	Frequent
	Knowledge of the system	Generally minimal	Moderate	High
	Flexibility of the system	Requires much flexibility	Moderately flexible	Structured, less flexibility
Information	Information focus	Futuristic, one aspect at a time	Whole organization	Single task/transaction
	Information complexity	Many variables	Less complex	Simple, rule-based
	Information structure	Unstructured, irregular	Rhythmic, procedural	Highly structured
	Nature of information	Tailor made, more external, and predictive	Integrated, internal but holistic	Task specific, real time
	Information scope	Long term	Long, medium, and short	Short term

We identify several challenges and opportunities for future studies on the perspective of evaluation. These challenges are ever more important, given the paradigm shift of developing systems for a number of user groups, instead of developing specialized systems for single user groups. First, researchers should identify the interested user groups prior to conducting their empirical assessments. As shown in Table 70.2 and the related discussion, it is evident that each user group has distinct needs that are quite different from one another. Thus, your data collection instruments (e.g., questions or survey items) must be developed with attention to the characteristics of the different user groups. Gable et al. (2008) suggest that certain user groups will be closely aligned with certain success dimensions. They argued, for example, that operational personnel will place a greater emphasis on certain success dimensions to the exclusion of others when they evaluated a system.

Second, there is a real challenge for researchers to identify the relevant respondent characteristics, other than those that relate to their general employment classifications. For example, factors like respondents' exposure with similar systems, their knowledge of the system in question, and their experience with similar industry sectors will all have an impact on how they evaluate a system.

Alternative classifications of user groups are another opportunity for the future research. For example, Sedera and Dey (2008) suggest an alternative classification of respondents based on their skills and degrees of proficiency. They devised a survey instrument—based on knowledge, socio-behavioral factors, and experience—to classify respondents based on degree of proficiency. Their study also suggested that groups with different degrees of proficiency will have different opinions of system success.

Another opportunity comes with the weighted average score of the respondent's views of the system. All past subjective system evaluation studies have treated scores of all respondents equally. This has meant that, regardless of the characteristics of the respondent, all respondents have an equal say of the system evaluation. From a management viewpoint, this is problematic and less valuable. A weighted-average scale would assign weights based on respondent characteristics and the dimensions of success on which they evaluate. When a group of respondents indicate a greater association, and familiarity, with a particular dimension of success, their scores on that dimension could receive a high weighting than the others (Gable et al. 2008).

Finally, we observe that there is potential for "collective" and "group-level" success studies. It has been widely accepted that system success in organization-wide systems depends heavily on the cooperative work of stakeholders, within and across the stakeholder groups. Thus, in addition to addressing success as an individual construct, there is potential to address it as a group-level, collective construct. As such, the questions will focus on "Has the IS helped improve the collective performance," rather than its success at the individual level.

70.4.3 WHY? The Purpose of the Evaluation

Gable et al. (2008) observed that organizations evaluate their information system (IS) for various reasons. A frequently asked question is "Has the IS benefited the organization?" or "Has the IS had a positive impact?" Positive impacts are the ultimate outcome measure of an IS; the "acid test" of the IS. These questions seek a measure of the net benefits or impacts to date; they look backward. The IS, being a long-term investment, is expected, other things being equal, to yield a continuing flow of benefits into the future. Thus other questions of interest include "Is the IS worth keeping?" "Does the IS need changing?" or "What future impacts will the IS deliver?" These questions are forward looking.

Serafeimidis and Smithson (2000, p. 97) reviewed the literature on IS evaluation and found that evaluations are done for a variety of reasons, including (1) "Establishing by quantitative and/or qualitative means the worth of IT to the organization and its growth," (2) "Ranking alternatives," (3) "Forming a central part of an incremental planning and control (diagnosis) process," (4) "Acting as an input to business and IS strategy formulation," (5) "Acting as a feedback function which assists organizational learning," (6) "Acting as a mechanism for gaining commitment and, in highly politically influenced environments, for legitimization," and (7) "Providing a deeper understanding of the interaction between the technology and the underlying organizational processes, culture and politics."

Davern and Kauffman (2000) emphasized the importance of understanding where the future potential value for an IT investment lies, in both project selection evaluation and post-investment evaluation. While evaluation usually has a positive role to play, evaluation can also be for political or social reasons (e.g., to reinforce an existing organizational structure) and be a ritualistic rather than effective process (Stockdale and Standing, 2006, p. 1093). Table 70.3 lists some of the reasons why organizations evaluate IS.

Similar to the scope of the system and stakeholders' opinion sought in an evaluation, the motivation of the assessment (the "why?") is an important aspect of a system evaluation. Yet, there is a severe dearth of studies where the purpose *of* the evaluation is linked to the measures employed *for* the evaluation. For example, the balanced scorecard approach supports this concept; in it, the measures employed in the assessment are derived from the strategy, vision, and mission of the organization.

TABLE 70.3 "Why" of Evaluation

Value Reasons	Leading To	Sources
Appraisal of value Measure of success Recognition of benefits	• Improvement in business goals • Organizational effectiveness • Investment management • Problem diagnosis • Consensus achievement • Decision making • Understanding risk • Gains in organizational and personal learning	Farbey et al. (1999) Mirani and Lederer (1998) Remenyi and Sherwood-Smith (1999) Serafeimidis and Smithson (1999) Serafeimidis and Smithson (1998) Hirschheim and Smithson (1998)

Source: Adapted from Stockdale, R. and Standing, C., *Eur. J. Oper. Res.*, 173(3), 1094, 2006.

As noted earlier, most IS success studies focus mainly on academic contributions, focusing heavily on construct validity and reliability. Thus, such studies rely heavily on constructs and measures that had been validated in prior studies in order to minimize the risk of introducing new measures that do not have a validated "lineage." This myopic focus on construct validation often means that the context of the study is ignored. A challenge—and an opportunity—for future IS success studies is to connect the purpose of the evaluation with the measures and constructs. This means that researchers could introduce new measures and constructs based on the purpose of the evaluation. Furthermore, future IS success studies have the potential to focus more on specific, diagnostic evaluations of an IS. This also means that researchers should be much closer to the study context, management, and user issues.

70.4.4 WHEN? The Timing of an Evaluation

The timing of a system evaluation could easily influence the evaluation outcomes. There seems to be a lag in the effects of IS investments; thus, it is important to consider when the evaluation is being done. For example, Hitt et al. (2002, p. 72) report that for enterprise systems there is "a slowdown in business performance and productivity shortly after the implementation." Markus et al. (2003) suggest there are two phases in an enterprise-system life cycle beyond the go-live date: (1) shakedown and (2) onward/upward. The period immediately after the go-live phase is the *shakedown* phase, during which users learn new system features and functions and adjust their work practices. The *onward/upward* phase follows the shakedown phase and reflects the finished, stable system. Organizations in this phase should see high user acceptance of the system and fewer ongoing technical issues. Also, from here on in, the organizations are also looking to derive additional value from their enterprise system investment through enhancements and value-adding functions. Markus and Tanis (2000) argue that the user experience and system success will be substantially different across these two life cycle phases. Ross and Vitale's (2000) study of 15 organizations found that all organizations underwent a "productivity dip" (p. 237) at the shakedown phase, while gaining productivity improvements in the onward/upward phase.

Researchers attribute the decline in productivity with a system to factors arising from users' lack of familiarity with the new system (Sumner 2000; Strong and Volkoff 2010). Several researchers have demonstrated that users, especially operational personnel, face a steep learning curve in the shakedown phase and it will take several years to master complex software features and functions (Mandal and Gunasekaran 2003; Botta-Genoulaz and Millet 2005). Therefore, during the shakedown phase, most installations restrict access to the system and operations by enabling only mandatory functions to be accessible (Kumar et al. 2003; Amoako-Gyampah and Salam 2004) until users develop a sufficient level of proficiency. On the other hand, users in the onward/upward phase receive more liberal access to value-adding system features and functions (Botta-Genoulaz and Millet 2005) through experience and practice. Social science researchers have identified years of experience, structure of the task, and "deliberate practice" as having a substantial influence on individual performance (Chi et al. 1988; Ericsson and Smith 1991). For example, Ericsson et al. (1993) demonstrate that an individual's performance is a monotonic function of the "deliberate practice" with the system.

Segars and Grover (1993) examined IT impact at an industry level. They found that "in each of the three industries examined no immediate impact was detected. Structural shifts were observed four to five years after the introduction of the technology" (p. 362). In relation to the timing and evaluation, we identify two main streams of opportunities for future researchers: researchers must (1) focus on the longitudinal evaluation of system success and (2) identify benefits in relation to the phases of the life cycle.

First, in relation to conducting longitudinal studies, we note that most IS success studies take a snapshot of the system performance at a point in time, typically using a survey instrument. Given the long-term view of IS in organizations, longitudinal studies will allow organizations to track IS performance over time. For example, despite research suggesting a dip in organizational performance following the go-live date, current research has yet to empirically test and demonstrate the changes to performance across the life cycle. Organizations often postpone an upgrade of aging applications, seeking

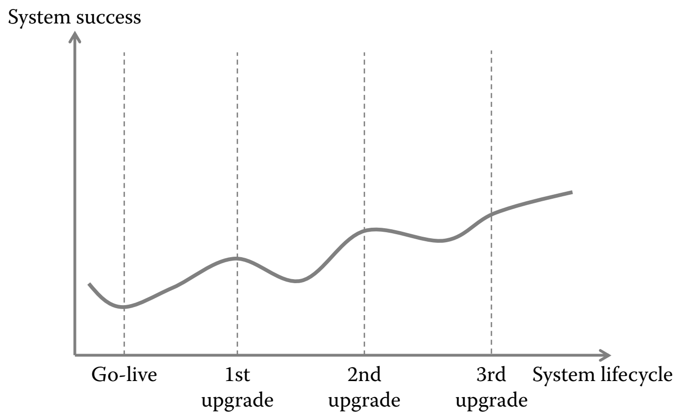

FIGURE 70.4 Systems life cycle.

to delay the relatively more tangible short-term costs. Yet, research by Gable et al. (2003) suggests that it is often optimal to upgrade an aged software earlier rather than later. A validated normative model (e.g., Figure 70.4) would aid organizations to better manage expectations of contemporary IS and to better plan mid- and longer term for evolution of the IS portfolio. This analysis essentially combines the measure(s) of IS success, positioning each application studied on the horizontal axis (the life cycle phase). Sensitivity analysis can then be conducted, through segmenting the overall study data into increasingly homogeneous segments.

Second, studies must continue to observe how benefits occur throughout the systems life cycle. Wang and Sedera (2011) conducted one of few studies that developed a benefits realization life cycle to demonstrate how IS success is achieved throughout the life cycle. Their study employed the DeLone and McLean constructs to illustrate how supply chain management system benefits appeared in a longitudinal study, proposing a benefits life cycle. For example, many studies have shown that the organizational benefits of an information systems will take time to appear, while the benefits from improved system and information qualities will appear earlier in the life cycle. However, it is unreasonable to assume that *all* of the measures of systems quality are realized at the early phase of the life cycle. Similarly, it cannot be assumed that all of the organizational-level benefits are only realized at the latter phase of the life cycle. Therefore, future IS success studies have a real opportunity and a responsibility to contribute to a better understanding of the timing of benefits. Empirical studies depicting a specific timeline for benefits realization using the phases of the life cycle are rare.

70.4.5 HOW? The Constructs and Measures of Success

The value of IT has been measured at various levels of analysis including the economy, industry, firm, business unit, business process, and individual (Barua and Kriebel 1991; Brynjolfsson and Yang 1996; Davern and Kauffman 2000). In the early days of information system, system performance was measured in terms of technical quality using observed speed and accuracy. When information systems evolved to be strategic, researchers looked to see the impact of a system to the organization. Dedrick et al. (2003) note: "For many years, there has been considerable debate about whether the IT revolution was paying off in higher productivity. Several studies in the 1980s found no connection between IT investment and productivity in the U.S. economy, a situation referred to as the productivity paradox. Since then, a decade of studies at the firm and country levels has consistently shown that the impact of IT investment on labor productivity and economic growth is significant and positive" (p. 1). Several researchers have studied productivity improvements through productivity, profitability, and customer surplus (Hitt and Brynjolfsson 1996).

At the industry level, Segars and Grover (1995) have shown how IT has evolved from part of the organizational overhead into a strategic resource capable of changing patterns of competition within industries. They examined the nature and change of structure in three industries during, and after, the introduction of strategic IT. Their findings suggest that in each of these industries, structural characteristics were dramatically altered subsequent to the introduction of competitive-based IT. Brown (2005, p. 169) found that "reported IS evaluation practice appears to be relatively unsophisticated or absent in many organizations." Barua et al. (1995, p. 21) demonstrated that "many of the significant IT impacts occur at low levels in the organization and they can be traced and measured."

Hamilton and Chervany (1981) discussed two different ways in which the success of information systems could be determined by organizations. One approach to evaluating IS success was a goal-centered approach in which the information system was examined to see if the system met the objectives specified by management. The second approach was a system-resource approach that considered the users and whether the system was serving their needs to facilitate communication, improve job satisfaction, or fulfill other needs beyond the primary organizational objectives. This approach highlighted the importance of evaluating information systems from a variety of perspectives including management, users, IS staff, and internal auditors (Hamilton and Chervany 1981).

Subscribing to the second approach, to measure the success of these various IS, organizations are moving beyond traditional financial measures, such as return on investment (Rubin 2004). In an effort to better understand the tangible and intangible benefits of their IS, organizations have turned to methods such as the balanced scorecard (Kaplan and Norton 1996) and benchmarking (Shang and Seddon 2002). Researchers have created models for success (DeLone and McLean 1992; Ballantine et al. 1996; Seddon 1997), emphasizing the need for better and more consistent success metrics.

In this stream of research, researchers have derived a number of models to explain what makes some IS "successful." Davis's (1989) TAM used the Theory of Reasoned Action and Theory of Planned Behavior (Ajzen and Fishbein 1975) to explain why some IS are more readily accepted by users than others. Acceptance, however, is not equivalent to success, although acceptance of an information system is a necessary precondition to success. Early attempts to define information system success were ill-defined due to the complex, interdependent, and multidimensional nature of IS success. The DeLone and McLean IS success model provides researchers and practitioners a model and an approach that focuses on such fundamentals. The remaining part of this chapter outlines future research opportunities based on the DeLone and McLean IS success approach and its applications.

70.4.6 Future Research Opportunities

There exist several opportunities for research in relation to the conception of the DeLone and Mclean IS success model. They include (1) providing a clearer view of the nature of the paths between the key constructs; (2) extending the validity and generalizability of the model constructs and measures; (3) providing a theoretical underpinning of the study model; and (4) improving model constructs.

70.4.6.1 Nature of the Paths between the Key Variables

There has been some criticism of the DeLone and McLean (1992) model for a lack of clarity about the relationships of the constructs—are the relationships among the constructs causal or process? In their 10 year update, DeLone and McLean (2003) responded that their model is both causal/variance and process. They argued that "A temporal, process model suggests that an IS is first created, containing various features, which can be characterized as exhibiting various degrees of system and information quality" (p. 11). Arguing that their model also shows variance/causal relationships, they state that "A causal or variance model studies the covariance of the success dimensions to determine if there exists a casual relationship among them. For example, higher system quality is expected to lead to higher user satisfaction and use" (p. 11). Yet, many users of the DeLone and McLean IS success model employ these constructs blindly, without any regard to the nature of the relationships among the variables.

This suggests that there are several opportunities for future research to extend our understanding of information system success as well as of the model itself. To begin, as demonstrated by Petter et al. (2008) in their meta-analysis of DeLone and McLean studies, no single study has ever addressed the complete DeLone and McLean model. Granted, this would be a rather large undertaking, and perhaps could be addressed in a series of related studies. Second, the nature of the relationship among the constructs provides an opportunity for future research on system success. For example, the necessary and sufficient causality of the model constructs is unclear in the DeLone and McLean model. According to Gable et al. (2008), the directions of the arrows between the constructs are unclear; therefore, one cannot be certain about the positive and negative relationships between the constructs.

70.4.6.2 Extending the Validity

Despite years of research on information systems success, including several hundred publications, there is still no single research study that has tested *all* the constructs and paths in the DeLone and McLean IS success model. Petter et al. (2008) state that "Most past studies focused on a single dimension of success, such as system quality, benefits or user satisfaction. Few studies measure and account for the multiple dimensions of success and the interrelationships among these dimensions." They further state "Until IS empirical studies consistently apply a validated, multidimensional success measure, the IS field will be plagued with inconsistent results and inability to generalize its findings." Gable et al. (2008) make this same observation, encouraging future research to engage in a more holistic approach in employing model constructs.

70.4.6.3 Theoretical Basis

Further opportunities exist in clarifying the relationships between the model constructs. For example, the causal relationship suggested in the model between constructs like system quality and benefits (or individual and organization benefits) requires a theoretical explanation. Moreover, the model does not provide a theoretical explanation for the time lags between constructs. These provide researchers with an opportunity to contribute to a further understanding of IS success.

70.4.6.4 Improving Construct Measurement

In addition to opportunities for improvements in the measurement of IS success variables, several conceptual improvements can also be made. First, researchers should minimize the issues surrounding the use of surrogate, self-reported measures and seek for objective measures to supplement or replace perceptual measures. There is a clear dearth of research in this area, with no studies found that employ objective measures to triangulate subjective measures. Furthermore, paying attention to model constructs that have not been well explored in past studies is another area for future research. Petter et al. (2008) identify use as one of the most under-studied constructs of IS success. Their meta-analysis identified that the relationship between each dimension and use is lower than associations with any other construct. They attribute this inconsistency of attention to the measurement and understanding of the use construct and argue that system use is an important indicator of system success.

70.5 Conclusion

In this chapter, we proposed several opportunities and challenges for IS success researchers. We began by introducing the DeLone and McLean IS success model as a point of reference. The DeLone and McLean model is one of the most widely cited academic studies in the IS domain. However, in spite of the success of the DeLone and McLean model and over three decades of active research on IS success, there are still many opportunities and challenges to the better understanding of information systems success. The body of knowledge for measuring IS success or performance in empirical studies has seen little progress during the past decade.

We presented our arguments for improvements using six considerations, describing each consideration, and followed by ways in which to move forward. We demonstrated that most IS success studies, with few exceptions, do not clarify the positioning of the study, thereby making it difficult to interpret them and use these evaluations for management purposes. First, we highlighted the implications of the evolution of the system. This is a major implication that must be taken into account for IS success studies. More and more corporate-wide systems are accessed through web portals or mobile devices, blurring the boundaries of traditional systems. We then presented several opportunities and challenges for IS researchers within this context. Next, we discussed the stakeholder views, the purpose of the evaluation, timing of the evaluation, and the measurement of success. Finally, we suggested research opportunities in relation to the reconceptualization and expansion of the DeLone and McLean success model.

Business Value of IS Investments

Ellen D. Hoadley

Rajiv Kohli
College of William & Mary

71.1 Introduction

The concept and constructs surrounding the business value of information systems (IS) have matured through the 1990s and into the twenty-first century. As data processing grew to information services and the data processing manager evolved to the chief information officer, evaluating the cost of technology has culminated in the valuation of the enterprise IS contributions, architecture, and innovations. The resultant question that the topic addresses is *How do we measure the ultimate impact that our expenditures on IS have on the strategic outcomes of the organization?*

This chapter provides an overview of the underlying principles, research findings, practical applications, and future trends in the efficacy and measurement of the business value of IS investments. Early efforts sought to determine tangible returns as evidenced in the financial statements. Current thinking posits that the investments yield strategic returns when skillfully applied by the chief information officer (CIO) with integrative and innovative vision within an organization that has the knowledge and abilities to use the investments. The understanding of the practice of measuring the business value of IS has moved systematically from the narrow focus of viewing IS as a collection of hardware and software that creates a technology capital investment to a collection of hardware and software that enables organizational processes that may be departmental or global to drive strategy. The former can be calculated succinctly to evaluate efficiency (doing things right); the latter is calculated at the organizational level to measure effectiveness (doing the right things).

71.2 Underlying Principles: What Do We Mean by "Business Value of IS Investments"?

Organizations measure their functional performance using metrics on the financial statements. Marketing is evaluated through revenues and market share. Improvements in operations are demonstrated through decreasing costs, return on assets (Kobelsky et al. 2008), and inventory turns (Dehning et al. 2007). Investments yield returns; profits increase dividends, retained earnings, and owners' equity. When thinking about the business value of IS investments, executives seek comparable metrics to evaluate whether or not the resources put into their information architecture have provided and/or are anticipated to provide tangible value. Additionally, traditional metrics of return on investment (ROI) are often conceptualized as tangible value realized from the actual technology purchase with less consideration of the differential returns resulting from employee development and process improvements (Im and Rai 2008). Generally, executives look at competing investments, the duration of potential payoffs, and the overall economic situation of the organization to justify expenditures in information technology (IT) (Weill 1992; Barua et al. 1995; Brynjolfsson and Hitt 2000; Devaraj and Kohli 2002). Increasingly, the focus of IS investments is on outcomes such as agility (Tanriverdi et al. 2010), flexibility (Saraf et al. 2007), risk management (Dewan and Ren 2011), and interfirm collaboration (Richey and Autry 2009).

Principle 1—The business value of IS investments is best viewed from both a variance and a process approach.
The variance approach to measuring the value of IS investment seeks tangible improvements in organizational metrics such as increased revenues or decreased costs (Weill 1992; Brynjolfsson and Hitt 2000). The process approach recognizes that even when the value of IS investment might be realized in traditional organizational metrics, firms may choose to pass the value on to their consumers as lower prices in order to sustain customer loyalty (Barua et al. 1995). The value of IS may not be identifiable with traditional financial statement metrics. The process approach seeks improvements in the processes affected by the IS investment and views internal process metrics as leading indicators of organizational value. Kohli and Hoadley (2006) present a theoretical framework (see Figure 71.1) that combines the two approaches. The framework recognizes the importance of overall organizational performance as a primary indicator of the value of IS investment while also providing a way to evaluate such an investment in an industry where competitive factors may mask that value or where the value realization may lag the investment by multiple time periods. Whether the business value of an IS investment is passed on to consumers, is mitigated by overall economic conditions, or is lagging the periodic reporting of organizational performance, the measurement of that value is still important to the strategic planning and decision making of the enterprise.

Principle 2—The business value of IS investments is best measured using balanced multiple metrics.
Metrics quantify the value of IS in ways that can be evaluated, compared, and improved. However, there should not be a single set of metrics. Instead, organizations can best measure the value of their IS investments by using and evaluating financial and operational metrics, tangible and intangible metrics, immediate and lagged metrics, and productivity, profitability, and customer value metrics. This may appear to be an overdose of measurement. However, when viewed as a balanced scorecard of metrics, the overall measurement provides the best opportunity to identify the interdependencies of the IS investments and organizational performance (Devaraj and Kohli 2002). Such a balanced scorecard approach would measure the value of the IS investment from the perspective of the customer, the efficiency of the operations, the external positioning of the firm, the innovative capabilities of the employees, and the financial return of the investments. Planning the best metrics to use to view IS investments from multiple perspectives supports the holistic evaluation and improvement of the organization's IS implementation.

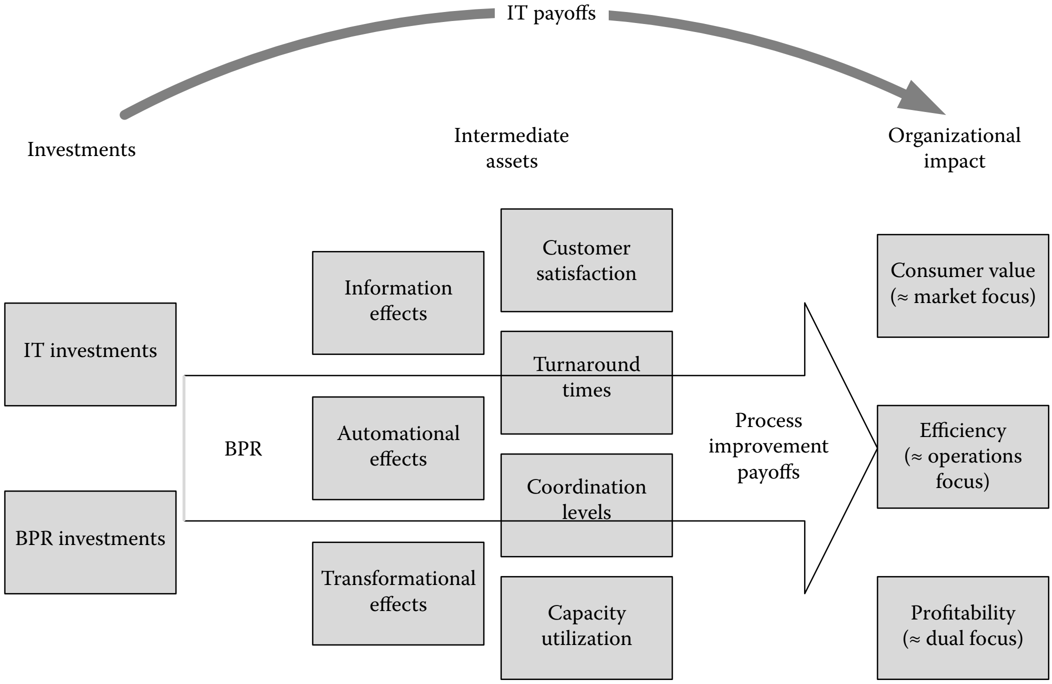

FIGURE 71.1 Process approach to information technology (IT) organizational impact. (From Kohli, R. and Hoadley, E.D., *DATA BASE Adv. Inf. Syst*., 37(1), 40, 2006.)

Principle 3—The potential for realized business value of IS investments depends on the position of the asset on the technology maturation curve.
Organizations must pay attention to the maturation curves of new technologies as well as assess their own comfort level with new "bleeding edge" technologies and with old tried-and-true technologies. The former technologies offer higher potential for process improvement and return value; the latter technologies offer lower risk of failure. Both may work in the organizational portfolio of interdependent systems, but all will be retired eventually. Organizations must align their technology adoption processes to the risk tolerance of the firm. Successful alignments have been made in organizations that are able to recognize and retire technologies that risk obsolescence, recognize competitors in related fields that may threaten the competitive landscape, and identify usability factors in a new technology that eases acceptance.

Strategic IS implementations may employ disruptive technologies, characterized as emerging technologies that are rapidly developing in ways that are attractive to a small segment of consumers (Bower and Christensen 1995) and are yet invisible to those enterprises that strive to stay close to their current customers. Disruptive technologies exploit novel attributes that are not desirable to current customers but that are quickly adopted by a new customer segment and that lure away a significant portion of the current customer base. Just as Blockbuster was challenged by Netflix and Research in Motion had to deal with Apple's iPhone, so will all organizations be required to be continually vigilant in their evaluation of emerging technologies. According to Gartner, within the next 5–10 years, augmented reality, crowdsourcing, and 3D scanners will be the norm (LeHong and Feng 2012). The values of these technologies are difficult to evaluate within an existing firm and often are viewed as having little or no value to a current customer base. To minimize the risk of disruptive technologies, the enterprise must be vigilant in understanding the strategic significance of its own existing technology portfolio as well as emergent technologies that present creative opportunities for competition.

Principle 4—The business value of IS investments is justifiable using multidimensional approaches.
Principles 1 through 4 lay the foundation for justifying an IS investment. This justification is essentially using the business value of an IS project to lay out the business case to promote investing in that particular project over alternative opportunities for investing the same funds. This is done by converting the value of an IS investment and its project payoff into a logical or mathematical form and comparing the factors of the project against similar factors in the alternative opportunities. Organizations employ differing approaches to justifying resources investment such as intuition-based models, cost-benefit analysis, break-even analysis, net present value, economic value added, and regression-based statistical analysis. For future opportunities, firms use real options–based methodologies to justify IS investment for which NPV or ROI cannot be calculated (Fichman 2004). Each of these approaches quantifies organizational factors of performance and uses these quantifications to compare potential investments. Another approach (Flatto 1996) enhances a net present value approach by incorporating risk management and investment changes into the model. Though each justification approach quantifies like factors of competing projects, the assessment of future value is likely to best predict achieve positive outcomes when approaches are combined to calculate a holistic evaluation with multiple dimensions rather than evaluating each project dimension separately.

Principle 5—Sustained measurement of IS value is accomplished through a comprehensive organizational process.
Measurement of the business value of IS investment is most meaningful when incorporating all factors of the project as implemented. This means that the project must be initially developed with measurement of business value incorporated into the work. One cannot wait until after user acceptance of an IS project before building the measurement structures and gathering evidence of the payoff. Further, when the value of IS investment emerges in other parts of the organization, demonstrating business value is not only the responsibility of the IS managers; rather, t is an organization-wide process (Kohli and Johnson 2011). Therefore, a comprehensive process of value measurement should span the phases from pre-investment to post-investment review.

An exploration phase develops an understanding of what is to be measured, how it will be quantified, and which data techniques are most appropriate for analysis. A discovery phase addresses organizational issues in order to maximize the managerial and political factors of IS business value. The analysis phase collects, analyzes, and reports the data that demonstrates the quantifiable portion of IS business value. The communication phase is the feedback loop that provides the information back to the organization as to the outcome of the analysis and the language that will be used to institutionalize a preference, culture, and bias of measurement of value. Using a comprehensive evaluation process makes the measurement of IS business value a quarter involved with data and three quarters involved with organizational planning, involvement, and communication. Many projects fail, even though they may employ analysis, because they fail in the organizational quadrants. Incorporation of all phases improves the probabilities of implementing demonstrable and sustainable value in one IS investment and supports a culture of linking together like investments over time.

Principle 6—Strategic integration of IS value measurement informs planning and decision making.
Following a process of measuring the business value of an IS investment does not guarantee strategic benefits. It is not until the value measurement is used for planning future strategic initiatives and making decisions for operational improvements that the business value is realized. Organizations must communicate the measurements across multiple levels and through multiple channels. Executive leadership uses measurement to identify immediate and lagging payoffs, to locate impacts that may occur outside the locus of the investment, and to communicate to stakeholders that the vision for the future is achievable through concrete actions that permeate the organization. The integration of business value with senior management motivation, planning, and decision making is an emerging area of research (Salge et al. 2011).

71.3 Trends in the Field

As the measurement of the business value of IS has evolved, different trends have emerged that have generated interest because of their practical application and importance to a fuller understanding. The first trend is a shift from measuring efficiency as a saving of time and materials to measuring effectiveness of the outcomes of systems. Though efficiency remains as an important base for improvement, organizations seek value in systems that achieve the desired goals for themselves, their suppliers, and their consumers. A second trend is the consideration of the sustainability of the business value of IS. It is important to realize first-time, one-time, and current value of the IS investment. It is also becoming more important to sustain that value as long as possible and to recognize the appropriate time to retire or transition an organizational system. A third trend incorporates the global effects of IS and views the business value of IS as the linking mechanism among strategic partners. The goal is to enable synergies that expand the capacities of organizations beyond those that are possible for each one alone. Finally, an emerging trend is to view the business value of IS investments in how they expand the total collection of resources of an enterprise. This view includes the possibility that IS investments enable creative and innovative opportunities above and beyond the streamlined processes of the organization. These opportunities are realized in combinations of organizational assets, strategic vision, and human creativity all synthesized using the firms IS. These trends represent an expansion of the base research presented in the underlying principles of the business value of IS and indicate areas of future investigation that are of interest to practitioners and researchers.

71.3.1 Shift from Efficiency Measures to Effectiveness Measures

The ideas surrounding the importance of the business value of IS have endured since the 1990s. In the 1980s, the Society for Information Management began annually to survey executives in IS to determine the key issues facing them. In 1996, in the midst of the ramp up to Y2K, 70% of the topics reported were issues of IS hardware and software (Brancheau et al. 1996). The issue that eventually was incorporated in the business value of IS—aligning the IS organization within the enterprise—was ranked #9. Since then, the topic label has become "information technology (IT) and business alignment" (Table 71.1). From 2005 to 2010, the topic has remained at or near the top of the list, currently sharing the spot with organizational issues such as "business productivity and cost reduction" and "business agility and speed to market" (see Table 71.1). Additionally, this topic has remained an important focus of study for IS academics as seen in conference proceedings and special issues of journals.

The practitioner press also has evolved in its view of the importance of IS value (Chillingworth 2010). For example, CIO magazine (Overby 2011) stated that those CIOs who want to remain part of a strategic company must shift from using IT simply as a tool to support the strategy of the firm. Likewise, the CIO must become a business leader who can understand business value and communicate the ways that IS can and does create, enhance, and enable that business value (Mitra et al. 2011). Businesses must develop strategy that deploys IT to connect the information assets to their decision makers and customers and then lead the communication of how those assets create value.

The shift from efficiency to effectiveness was presented early on (Soh and Markus 1995), bringing together the constructs of process measurement and IT metrics. The process of the realization of value from investments in IT was articulated as follows: IT expenditures lead to IT assets that have IT impacts that are subsequently realized as organizational performance. The IT expenditures and organizational performance had normally been measured as part of the financial statement. Understanding the intermediate measures provided a way to understand the time delay and mitigating factors between the cause and effect of the variables.

To link efficiency to organizational performance, three categories of metrics were articulated: productivity, business profitability, and consumer surplus (Hitt and Brynjolfsson 1996). The fact of measuring

TABLE 71.1 MISQ Executive Key Issues

MISQ Executive Key Issues for IS Executives (2005–2010)	
2010	• Business productivity and cost reduction
	• Business agility and speed to market
	• IT and business alignment
	• IT reliability and efficiency
	• Business process reengineering
2009	• Business productivity and cost reduction
	• IT and business alignment

	• Business process reengineering
	• IT cost reduction
2008	• IT and business alignment
	• Build business skills in IT
	• IT strategic planning
	• Attracting IT professionals
	• Making better use of information
2007	• Attracting, developing, retaining IT professionals
	• IT and business alignment
	• Build business skills in IT
	• Reduce the cost of doing business
	• Improve IT quality
2005	• IT and business alignment
	• Attracting, developing, and retaining IT professionals
	• Security and privacy (tied with above)
	• IT strategic planning
	• Business process reengineering

at the organization level moved the metrics into the realm of the c-level executives and beyond the limited scope of the CIO. Adding consumer surplus brought the measurement focus on effectiveness. If the IS investments were effective, the organization's customers could realize improvements from those investments. Understanding these organizational performance metrics provided a way to incorporate a broader concept of value to include effectiveness. Additionally, consumer surplus could explain why an organization could realize a large value of effectiveness from IS investments but not see it in profitability because it had passed the value on to its customers.

The interaction between IT implementation, business process reengineering (BPR), and organizational performance was examined across over 300 firms between 1996 and 1999 (Ramirez et al. 2010). The results indicate that synergies between IT and BPR implementations result in improved productivity efficiency and improved market value. These findings support the importance of both efficiency and effectiveness at the organizational level when measuring the business value of IS.

One component of measuring effectiveness is evaluating increases in intangible assets (Tambe et al. 2011). These intangible IT assets include a firm's work practices, information structures, and employee-skill mix that are ancillary to the tangible IT investments. Research in a longitudinal study found that the quantity of intangible IT assets increased from 1987 through 2005 making those assets available for future productivity gains for the organizations. The accompanying low levels of depreciation of the assets indicate a stockpiling. It was concluded that investment in these intangible assets is linked to the growth of significant productivity and should lead to growth. Yet, the importance of these findings is the articulation of specific metrics of intangible IT assets that lend themselves to quantitative analysis similar to tangible assets.

In spite of the years of research into the business value of IS, the concepts, terminologies, and findings remain fuzzy. Some small portion of the perception of long-term vagueness is the reality that "years of research" in the field of IS is not actually as long as "years of research" say, in medieval Scottish poetry. However, it is problematic that theory remains underdeveloped and loosely applied (Schryen 2010). To fully comprehend the phenomenon of the business value of IS for efficiency and effectiveness, programs of research must link studies together and should strive to progressively expand the body of knowledge. Literature reviews must use the theoretical base as a skeletal framework to tie the literature together in a meaningful way that creates knowledge with predictive and explanatory power.

71.3.2 Sustaining the Business Value of IS over Time

An additional focus of research in the area of the business value of IS is that of value sustainability. Organizations may or may not realize immediate or even lagged value from their investments in IS. However, a greater challenge may be to sustain those improvements in effectiveness as seen in profitability, productivity, and consumer value. An examination of firms across multiple industries receiving awards for their realization of value from their IS investments (Masli et al. 2011) looked for improvement of organizational performance over time as well as the duration of improvements. Structural shifts such as Y2K and the dot.com era slowdown caused many of these firms to lose momentum at the turn of the century. However, the study shows that since that time, many of the firms have struggled to sustain the realized value of their IS investments.

Of particular interest are those firms striving to employ sustained IS investment to achieve a low-cost position in a competitive environment (Tallon 2007). The challenge comes from the commoditization of the IT infrastructure that is more easily replicated by others. Those firms that have achieved a level of business value sustainability are those firms with multiple successful IS implementations. This confirms the principle that measuring business value of IS is best accomplished using multiple metrics at the organizational and process levels (see Figure 71.1), and that a culture of using IS to achieve organizational goals contributes to sustaining the business value.

71.3.3 Business Value of Inter-Organizational IS

As businesses seek new ways to achieve their missions and goals, they find that viewing themselves as singular entities competing among others limits their opportunities for success. Firms that seek strategic partners to achieve shared aims realize increasing returns through implementations of interoperable systems. An emerging research question (Grover and Kohli 2012) is asking how separate organizations can exploit their inter-organizational IS to realize values to each that neither could realize on its own. The relational view proposed in the strategy literature (Dyer and Singh 1998; Dyer 2000) presents a model of four factors that relate to value co-creation within multiple organizations:

- *Relationship-specific assets* are those shared assets that enable value co-creation to those firms in the partnership and are protected to ensure their use being limited solely to those organizations.
- *Complementary resources and capabilities* are those within one or more of the organizations in the partnership that enable value co-creation within the partnership but which could not enable value co-creation solely within one of the organizations.
- *Knowledge-sharing routines* enable shared information and expertise to inform value co-creation.
- *Governance* includes contracts and financial protections that streamline costs and boost the incentives for value co-creation.

While numerous examples of these factors and concepts exist, research into value co-creation has a broad horizon of opportunity to add to current theory for expanded understanding and application.

71.3.4 Capabilities of the Firm vs. a Systems Theory View

An alternative framework for understanding and examining the business value of IS is based on the creation of capabilities within a firm (Nevo and Wade 2010). In this framework, existing research takes a resource-based view of the firm explaining that such a view assumes that firms compete based on their own organizational resources. Those organizational resources that have the potential for strategic improvement of the firm must have value, rarity, inimitability, and nonsustainability (Barney 1991). Since IT assets are available and replicable, the strategic potential is minimal. Instead, it is the IS resources that have those factors for creating and sustaining competitive advantage. Therefore, much of the literature that has focused on the business value of IT instead should look at the synergies created between *organizational* characteristics and IT assets for examining the organizational impact.

IT-enabled resources [and IS assets] are developed when IT assets and organizational resources join to achieve effective mission performance (Nevo and Wade 2010). The emergent capabilities may be predicted or not and may have a positive, negative, or neutral impact on the firm. Those positive emergent capabilities are labeled as *synergy* and are sought to achieve organizational goals. The research in the business value of IS should determine the factors in why some potential emergent capabilities are synergistic and others fail to achieve positive outcomes.

Currently, firms face hypercompetition where the industry is marked with products and services that evolve dynamically and stretch the competitive environment of the business. In these organizations, the business value of IS is realized when it supports the ability of the firm to adapt its processes and information flows along with these dynamically evolving products and services (Tallon et al. 2002; Tanriverdi et al. 2010). The adaption includes seeking new areas of competitive advantage while sustaining old products and services only so long as they sustain their business value. The adaptation is mirrored by evolving IS that sustain a series of competitive advantages over time. There is additional evidence that a flexible IT infrastructure that is aligned with the organization's strategic goals yields organizational agility critical to the achievement of those strategic goals (Tallon and Pinsonneault 2011). The overall IS support of business competition plays out like a concerto with slower and faster movements, yet with a sustaining theme of business value.

71.4 Evolving Role of CIO

In addition to measurement of business value of IT, the focus increasingly has been on the organizational structure and the role of the CIO in realizing the value that technology provides to the organization. Recent research has indicated the diverse and occasionally multiple roles of the CIO that have evolved since its inception (Carter et al. 2011). It is the CIO who is charged with recognizing future trends in business and technology; it is the CIO who provides the leadership in realizing the value of the IS investment (Kohli and Johnson 2011) and whose role in the organization is likely to influence business performance (Banker et al. 2011). This leadership role is required within the IS function for system deployment and within the business as a whole for developing technology-enabled strategy (Chen et al. 2010).

The development and focus of the efforts of the CIO were chronicled by Hoadley and McFadden (2010), concluding with the concept that the CIO, to remain relevant, needs to become the chief information innovation officer of the organization. Early data processing managers focused on hardware and software, efficiency of processing, and minimization of downtime of the systems. In 1995 when organizations were beginning to reduce their silo structures by looking at their processes, IS and business executives were called to form partnerships to improve the success of their reengineering efforts (Martinez 1995). A blueprint for building such a partnership was presented that shifted the activities of the CIO from solely managing the IS function internally to aligning the management of IS and business strategy.

Today, the focus has shifted from technical efficiency to strategic leadership. The CIO is to guide the enterprise in its collection and dissemination of vast amounts of internal and external data in

information-rich, immediately available, and user-specific formats that lead to timely and strategic decision making. The CIO becomes the executive-level systems thinker who can communicate the value of IS in nontechnical, business-impacting terms that provide direction to the organization. The strength of IS leadership is grounded in a partnership between the IT and business functions with particular attention to strategic planning and after-action-reviews of IS implementations (Tallon 2008).

The strategic leadership role of the CIO is particularly challenging in those firms dominated by specialized mechanization and complex capital investments (Kohli and Johnson 2011). Traditionally, these organizations have used these internal structures to create barriers to entry. The downside of these structures is the limited flexibility, which is antithetical to the nimble processes that are the hallmark of the digital economy. Building operational excellence into redesigned business processes requires both a holistic view of the organization and a technical savvy raising the CIO function to strategic visibility.

The maturity of an enterprise will be modeled around an information orientation in which the effective use of information permeates the decision making at all levels (Kettinger et al. 2011). The CIO serves as a strategic partner with others in the executive suite to create a culture that exploits information management to increase competitive advantage. The leadership model (Figure 71.2) demonstrates the leadership positions that can drive the organization to an implementation of information orientation (IO) for strategic advantage. With corporate examples, the information orientation guidelines are presented to the CIO to use to assess the firm's current position, to decide whether to assume leadership, and to select a leadership style appropriate for the firm. Once leadership is assumed, the CIO must determine how to mobilize resources to improve the organization's effectiveness in realizing the business value of IS.

CIOs should use the specific metrics and language to communicate the value of IS within the organization (Mitra et al. 2011). The metrics are grouped into five domains that address those business categories that are important to executives. Using the guidelines provided, the CIO can lead the development of a set of metrics that are key performance indicators of IS value and use these indicators to improve the impact of IT within that enterprise. The use of these guidelines supports the use of organizational business value measurement with the communication tools to provide the feedback loop for improvement.

71.5 Future Impact on Practice

Practitioners will experience profound effects of measuring the business value of IS. What once was perceived as the *productivity paradox* has become a language and understanding that deploying a supportive and flexible information architecture informs users about the content and context of real-time decision making (Weiss 2011). Some organizations seek to reduce the fragmentation of their systems through the use of an integrated enterprise architecture (Bradley et al. 2011). The architecture is logically designed to link technologies and business processes for current and planned IS development thereby "informating" those processes for strategic purposes. Whether executives choose to implement such a technology/process coupling or choose to implement processes that integrate disparate systems, the interdependencies of technologies and processes require adroit management to yield high value. It is the integrative executive who will lead the most successful organizations to realize the high business value of IS investment.

71.6 Future Research

A review and synthesis of the research literature articulated a theoretical framework in which the business value of IS takes into account the context of the enterprise (Melville et al. 2004). The framework recognized that a firm, as well as its competitive and macro environments, encompasses multiple factors that contribute to and are affected by the organization's performance. To address these factors, the authors posed multiple research questions that have shaped the framework of the business value of IS within those environments.

A consolidation of research synthesized the collection of findings that remain pertinent (Kohli and Grover 2008):

- IT does create value.
- IT creates value under certain conditions; numerous factors mediate IT and value creation.
- IT-based value manifests itself in many ways.
- IT-based value is not the same as IT-based competitive advantage.
- IT-based value can be latent.

From this baseline research, themes were developed to demonstrate the evolution of IT's value and how it is captured, measured, and communicated (Kohli and Grover 2008):

- Theme 1: *IT-based co-creation of value*. How can organizations with different or new IT resources co-create value and equitably partake in the IT-based value?
- Theme 2: *IT pervasiveness*. How can we digitize various functional and dynamic business capabilities in order to increase business value under various conditions? Can these capabilities be replicated and sold as products?
- Theme 3: *Information mindset*. How can we create information capabilities that enhance and do not destroy digital business capabilities?
- Theme 4: *Value expansion*. What are the indirect and intangible paths to economic value that can be influenced by information and IT capabilities, and how do we foster them? Value expansion includes flexibility, agility, inter-organizational collaboration, and risk management.

The investigation of IS investment to mitigate risk as part of the value expansion theme has emerged from the application of real options theory (Tallon et al. 2002; Lankton and Luft 2008). Real options theory takes into account the ability of a decision maker to be flexible and adaptable in making IS investments. The challenge of measuring business value in a chain of investments designed to mitigate risk is that the best thing that can happen is nothing; i.e., sometimes a firm will invest in IS to reduce or eliminate the probabilities of adverse events. The hard metric becomes the estimated cost of potential failure compared to the investment to achieve no failure, reduced exposure to risk, and/or reduced cost of insurance coverage.

Though quantifiably challenging, the application of this type of IS investment is evidenced in practice, specifically in the healthcare industry to improve estimates of complication rates and to reduce malpractice insurance premiums (Menon and Kohli 2012). On the downside, there is additional evidence that the investment in IS may create legal evidence of malpractice, which could increase exposure to risk and malpractice insurance premiums (Ransbotham and Overby 2010). These alternative findings indicate that the IT itself is value neutral, but the IS investment may yield quantifiable risk and mitigation options.

As research has expanded into the areas mentioned earlier, the IT co-creation of value has warranted particular attention. A special issue of *MIS Quarterly* in 2012 presented multiple studies that focus on the particular factors that enhance the development of business value when intangible and tangible IT assets work together. A continuing question of interest is whether or not investments in IS creates measurable improvements in profitability, productivity, and consumer value (Mithas et al. 2012). Yet increasingly, studies explore how inter-organizational systems create and sustain business value for participating partners (Han et al. 2012; Rai et al. 2012; Sarker et al. 2012). The issue includes an essay (Constantinides et al. 2012) proposing that future research consider the pragmatic ends that studies can and should address as well as the decisions that are made regarding data collection, experimental design, and ultimate impact of investigations. The broader question of relevance vs. rigor remains as valid now as it was when the IS field emerged.

Future research also will expand the IS field into interdisciplinarity. Just as organizationally implemented systems expanded into inter-organizational systems and creation of business value expanded into co-creation of business value, so does the field of IS continue to expand into its close business disciplines and broader behavioral disciplines. Ethical questions remain about co-creating value for those who are separated from access to that value as the digital divide separates “have” from “have-not” and digital natives from digital immigrants. What particular value do specific emerging technologies provide? How does consumerization of IS, where the boundaries of personal and professional processes are blurred, influence our value perception of IS and IS investment? How do we create value within virtual business processes such as online diagnosis and planning tools? Is IS value creation different or the same in virtual organizations? These broader questions will require broader thinking to yield greener pastures of study. Yet this is the promise of the future that IT and IS are no longer systems for their own sakes. Instead, they are value-development tools of the business and organizational future. As the speed of technology increases, and the reach of global processes expands, so must our understanding of technical systems combined with human innovation synergistically increase the power organizations to achieve their goals.

71.7 Summary

The study of the business value of IS emerged as a topic of interest as IT infrastructure and personnel have become deeply embedded in business processes. Once it became clear that organizations rely on their IS investments to conduct transactions, make decisions, and monitor their environments, justification of expenditures led to the application of financial analytics to support the investments. Yet large amounts of incoming data (e.g., from social media), the pervasiveness of the technology, and IT’s central role in process enablement have exposed limitations of currently available analytical tools. Organizations continue to seek explanations and knowledge from the IS research community to identify how to assess the value of investing in IS vis-à-vis other demands and opportunities for investment. Early studies viewed narrow departmental applications as capital expenses to be amortized and depreciated. Organizational systems enabled interdepartmental processes measuring effectiveness at the firm level. Organizations have come to realize that combining the technology infrastructure with the human capabilities expanded the performance of the assets synergistically. This realization has broadened the investigation of how IS investment creates value for the business.

Currently, organizations continue to justify their expenditures in IS. However, recent innovative uses of IS indicate that the focus of the justification must be on how the organization can

use systems to enable and expand business strategy and forge strategic partnerships as a basis for competitive advantage for all the partners and for the consumers. The IS value is embedded within business processes and in inter-organizational, inter-stakeholder processes with the lines between personal and professional applications increasingly blurred. As the technology becomes inseparable from the processes, the enterprise will continue to measure and evaluate the business value of IS through novel ways that may include intangible measures for agility, collaboration, and risk mitigation.

Information Technology and Firm Value: Productivity Paradox, Profitability Paradox, and New Frontiers

Sunil Mithas
University of Maryland

Henry C. Lucas, Jr.
University of Maryland

72.1 Introduction

Interest in the business value of IT has been a dominant theme in the information systems literature since its early days. The literature on IT value has expanded considerably from its origins in the 1970s (Lucas 1975a,b). IT has become far more pervasive throughout the economy since 1970s, changing the way firms do business, enabling new business models that are creating value, and altering everyday life through social networking and Web 2.0 applications (Lucas 2008; Mithas 2012). Our goal in this chapter is to review what the field has learned in the last 40 years and discuss future opportunities for research (see Table 72.1 for several prior reviews of this literature).

Our conclusion is that there is no question any longer that IT, if properly deployed, creates value for organizations and society. We now have a much better understanding of how IT contributes to value, but the changing nature of IT raises some new questions. How do organizations incorporate rapidly developing technologies into their business models? What new kinds of services and products does the technology make possible? How should incumbent firms respond to new technologies that may destroy their value; for example, how does management avoid the outcomes that have befallen Borders, Blockbuster, and Kodak? These and many other related questions make the business value of IT research an enduring, interesting, and exciting area for researchers and practitioners.

TABLE 72.1 Selective Meta Review of Review Articles on "Business Value of IT" Literature

Study	Time Period and Focus of Review	Key Findings	New Opportunities for Research Identified in the Article
Lucas (1993)	1960–1991, Historical perspective on the business value of IT	• Technology should be suitable to the situation in which it is used • To demonstrate business value, the organization and individuals must use technology in an appropriate manner	• Studies of the deployment of one type of technology and of its users during system implementation offer the best chance to demonstrate that an investment in IT has business value
Brynjolfsson (1993)	1983–1993, Empirical studies of IT and productivity	• IT productivity paradox might be due to four reasons: mismeasurement, lags, redistribution, and mismanagement	• Researchers must be prepared to look beyond conventional productivity measurement techniques
Brynjolfsson and Yang (1996)	1982–1995, Empirical studies of IT and productivity	• Several studies document IT's positive effect on productivity performance	• There is little evidence of a positive contribution from IT to other performance measures such as profit and market value
Brynjolfsson and Hitt (2000)	1987–2000, Empirical studies of interaction of IT and organizational complements on productivity	• Organizational capital complements IT investments to increase performance	• Measuring the intangible components of complementary organizational assets
Barua and Mukhopadhyay (2000)	1963–1999, Studies on "process-oriented" and production function approach	• A positive contribution does not tell us whether we over- or underestimate IT impacts • Complementarity between IT and other factors	• Can we empirically distinguish between firms that make identical investments in IT but that may obtain very different returns from such investments? • What are some key factors that might have been ignored in production function and business value studies?
Dehning and Richardson (2002)	1990–2002, Archival studies that use accounting or market measures of firm performance	• Proposes a framework for IS research by suggesting that IT has a direct or indirect effect on business processes, which together determine the overall performance	• Examining the relation between IT and business processes, and business processes and overall firm performance • Understanding the effect of contextual factors on the IT-performance relation • Examining the IT-performance relation in an international context • Examining the interactive effects of IT spending and IT management on firm performance
Dedrick et al. (2003)	1985–2002, Empirical studies based on economic analysis on IT productivity	• At both the firm and the country level, greater investment in IT is associated with greater productivity growth • IT-performance relationship at the firm level can be further explained by complementary investments in organizational capital	• Understanding of the mechanisms by which IT pays off in higher productivity • IT spillover effects • Further examine the IT and profitability relationship • Excess returns at the firm level • Timing of payoff from IT investments • Industry differences on IT returns

TABLE 72.1 (continued) Selective Meta Review of Review Articles on "Business Value of IT" Literature

Study	Time Period and Focus of Review	Key Findings	New Opportunities for Research Identified in the Article
Kohli and Devaraj (2003)	1990–2000, 66 firm-level empirical studies on IT value	• Meta-analysis • The sample size, data source, and industry in which the study is conducted influence the likelihood of finding positive IT effects on firm performance	• Measuring the payoff accruing to partners using a process measurement approach • Gathering larger samples comprising of longitudinal or panel data to assess the lag effects of IT payoff
Kohli and Grover (2008)	IT business value literature at the level of the firm or network of firms	• IT creates value under certain conditions • IT-based value manifests itself at many levels • IT-based value is not the same as IT-based competitive advantage • Causality for IT value is elusive	• How can companies with different or new IT resources co-create value and equitably partake in IT-based value? • How can we digitize various functional and dynamic business capabilities to increase business value? • How can we create information capabilities that enhance and do not destroy digital business capabilities? • What are the indirect and intangible paths to economic value that can be influenced by IT capabilities?

72.2 Phases and Foci in Business Value of IT Research over Time

Because the onset of modern computing started in 1950s, information systems is a relatively young discipline, compared to other disciplines found in business schools. The field started to create an identity in the 1960s. Gordon Davis wrote one of the first books to introduce business students to computers in 1965. Subsequently, Gordon Davis, Gary Dickson, and Tom Hoffmann started a program at the University of Minnesota in 1967 to offer a master's degree and a PhD in Management Information Systems (Davis 2009). The Sloan School at M.I.T. had a large group of IS faculty in the late 1960s and offered a PhD in information systems. The University of Arizona, NYU and Purdue University also started PhD programs in 1970s. The first premier scholarly journal of the discipline *MIS Quarterly* was launched in 1977 with Gary Dickson as the editor and Hank Lucas as associate editor. The first conference in information systems, ICIS, started in 1980. INFORMS launched the other premier journal of the field, *Information Systems Research*, in 1990.

With this backdrop of the evolution of the discipline, we trace the development of business value of IT research in three overlapping phases over time.

72.2.1 First Phase from 1970s until the Mid-1990s

The first phase of IT value research from 1970s till late 1990s focused on the so-called productivity paradox (Lucas 1999; Panko 1991). During this period, academic studies and the business press periodically revisited this so-called paradox of computers. The productivity paradox referred to the phenomenon that, on the one hand, computing power in the U.S. economy increased significantly over this period, but on the other hand, economy-wide productivity, especially in the service sector, seemed to have stalled. For example, the average labor productivity growth in the U.S. economy averaged only about 1.4% from 1973 to 1995 (Brynjolfsson and Saunders 2010).

Many economy-level studies found broadly negative correlations of IT with productivity. Econometric estimates also suggested low IT capital productivity in different industries (Brynjolfsson and Yang 1996; Loveman 1994; Roach 1991). Multifactor productivity growth, which takes into account changes in capital, had also declined significantly during the period (Baily 1986). The overall negative correlation between economy-wide productivity and the advent of computers was used by some to argue that information technology did not help U.S. productivity or even that IT investments were counterproductive (Baily 1986). This link was further supported by Stephen Roach's (1987, 1991) research focusing specifically on information workers across industries. Roach cites statistics indicating that output per production worker grew by 16.9% between the 1970s and 1986, while output per information worker decreased by 6.6%.

Industry-level studies also suggested that most of the productivity slowdown was concentrated in the service sector (Roach 1987, 1991). Because services use a significant part of computer capital, this was taken as indirect evidence of poor IT productivity. Roach's widely cited research on white collar productivity, discussed earlier, focused principally on IT's performance in the service sector (Roach 1987, 1991). Studies using data from manufacturing also found evidence of a productivity paradox. Berndt and Morrison used a dataset from the U.S. Bureau of Economic Analysis (BEA) that covers the whole U.S. manufacturing sector. Morrison and Berndt (1991) found evidence that every dollar spent on IT produced, on average, less than one dollar of value on the margin, indicating a general overinvestment in IT. They also examined broad correlations of IT with labor productivity and multifactor productivity (Berndt and Morrison 1995) and did not find a significant difference between the productivity of IT capital and other types of capital for a majority of the 20 industry categories.

Some firm-level studies also examined the relationship between IT investment and productivity. Among studies of IT's impact on the performance of financial services firms, a study by Parsons et al. (1993) estimated a production function for banking services in Canada and found that the impact of IT on multifactor productivity was quite low between 1974 and 1987. Another study looked at data on the insurance industry and found a positive, but quite weak, relationship between IT expenses and various performance ratios (Harris and Katz 1991). Among firm-level studies of IT productivity in the manufacturing sector, Loveman (1994) estimated that the impact of IT capital on output was approximately zero over the 5 year period studied in almost every subsample he examined. Weill (1992) was able to disaggregate IT by use. He found that significant productivity could be attributed to transactional types of information technology, but he was unable to identify gains associated with strategic systems or informational investments.

Researchers proposed several explanations for the so-called IT productivity paradox: (1) mismeasurement of outputs and inputs, (2) lags, (3) redistribution and dissipation of profits, and (4) mismanagement of information and technology (Brynjolfsson and Yang 1996). Some even argued that given measurement errors and the nonautomatic nature of payoffs, it was time to stop conducting general IT impact studies for the entire economy and, instead, consider studies of the management of IT impacts for departments, individual firms, and individual users (Panko 1991). Subsequent research addressed some of these issues and led to resolution of the original "productivity paradox" while observing some new paradoxes.

72.2.2 Second Phase from Mid-1990s until the Early 2000s

The second phase of value research from mid-1990s till mid-2000s (and continuing) used newer datasets and more sophisticated methodologies. Some of these studies documented IT's positive effect on productivity (see Table 72.2). Lichtenberg (1995) reported positive effects of IT based on output. Brynjolfsson and Hitt (1996) confirmed the results of Lichtenberg (1995) and their own prior study (Brynjolfsson and Hitt 1995) using the same data source and similar methods based on output and consumer surplus measures.

This phase also began to focus on intangibles, and some of this literature observed a "new productivity paradox" (Anderson et al. 2003). The use of the word "productivity" may not have been entirely accurate here because researchers were characterizing high valuation multiples on Y2K spending, which ranged from 31 to 45 for 1999 to 2002 (about 3–4 times that on R&D spending) as the new paradox of too high returns on IT (Anderson et al. 2003). Tables 72.3 and 72.4 provide a summary of these studies.

TABLE 72.2 Selected Empirical Studies Linking IT and IT-Enabled Capabilities with Productivity

Study	Sample	IT Variable	Dependent or Intermediate Variables	Key Findings
Tambe et al. (2012)	Survey of 253 firms in 2001 matched with IT employment data	IT employment	Product development and productivity	Test a three-way complementarities model that indicates that the combination of external focus, decentralization, and IT is associated with significantly higher productivity. In contrast, firms that have only one or two of these organizational practices in place, instead of all three, are not more productive than firms with none of them
Tambe and Hitt (2012)	1800 firms across 20 years (36,000 firm-years from 1987 to 2006)	IT personnel counts	Value added (sales minus nonlabor variable costs)	IT returns are substantially lower in small- and mid-sized firms than in Fortune 500 firms and materialize more slowly in large firms. The measured marginal product of IT spending is higher from 2000 to 2006 than in any previous period, suggesting that firms, and especially large firms, have been continuing to develop new, valuable IT-enabled business process innovations.Furthermore, the productivity of IT investments is higher in manufacturing sectors
Brynjolfsson and Hitt (1996)	1987–1991	IS spending	Sales	Average marginal product of computer capital was 81% compared to 6.26% for noncomputer capital. Attribute to hidden IT capital and organizational capital

Several studies have stressed the need for better theoretical models that trace the path from IT investments to business value (Bharadwaj 2000). These researchers adopted a "process-oriented" view that examines the effects of IT on intermediate business processes (Barua et al. 1995; Melville et al. 2004; Tallon et al. 2000).

Other researchers proposed that the positive effect of IT on intermediate variables can be examined through internal firm processes, inter-organizational relationships, and customer relationships. First, some studies suggested that IT enables greater automation, streamlining, and rationalization of processes (Santhanam and Hartono 2003). Better governance of systems and streamlined processes also enable firms to make better and more accurate use of their data—leading to improved analytical models and inferences (Davenport 2006) and more effective strategic decision making. IT investments can also facilitate innovation in products and services to help firms leverage organizational learning and knowledge (Kleis et al. 2012; Ravichandran et al. 2011; Tippins and Sohi 2003).

Second, IT investments can also enhance business processes critical in inter-organizational partnerships such as supply-chain relationships and corporate alliances. IT infrastructure provides firms with the ability to implement shared transaction processing and supply chain management across organizational boundaries (Mukhopadhyay and Kekre 2002; Whitaker et al. 2007). IT also makes it possible to reduce transaction hazards that could arise within inter-organizational relationships (Kim and

TABLE 72.3 Selected Empirical Studies Linking IT and IT-Enabled Capabilities with Firm Risk and Returns

Study	Sample	IT Variable	Dependent or Intermediate Variables	Key Findings
Li et al. (2012)	2004–2008 data with 5230 firm-year observations	IT control quality, types of IT material weaknesses	Management forecast accuracy	Firms with IT material weaknesses in their financial reporting system are associated with less accurate management forecasts; systems with IT material weaknesses related to data processing integrity have the least accurate management earnings forecasts
Dewan and Ren (2011)	1987–1994 data over 500 Fortune 1000 firms	IT capital	Firm return and firm risk	Suitable boundary strategies can moderate the impact of IT on firm performance in a way that increases return and decreases risk; this interaction effect is strongest in service firms, in firms with high levels of IT investment, and in more recent time periods
Kim et al. (2012)	1995–2002 data	IT investments	Bond rating and yield spread	Bondholders have different perspective toward risk than equity investors; lower bond ratings and higher yield spread in transform industries than in automate or informate industries
Henderson et al. (2010)	1991–2005 data from *InformationWeek*	IT investments	Market value, accounting performance, firm risk, abnormal stock returns	Information about a firm's IT expenditures help explain its future performance in terms of accounting measures and market measures; mispricing is attributable, at least in part, to the lack of adequate and verified information about firms' investments in IT
Kobelsky et al. (2008)	1992–1997 data from *InformationWeek*	IT investments	Earnings volatility	IT investments increase the volatility of future earnings; this impact is highly contingent upon sales growth, unrelated diversification, and size
Dewan et al. (2007)	1987–1994 data on over 500 Fortune 1000 firms	IT capital	SD (daily stock returns) and SD (realized annual earnings for 5 years after investment), market value of firm	Attribute high returns on IT to higher IT risk. About 30% of gross return on IT investment is due to risk premium associated with IT
Dewan and Ren (2007)	1996–2002 event data	Electronic commerce announcements	Risk-adjusted abnormal return	Wealth effects are not significant after controlling for contemporaneous risk changes

TABLE 72.3 (continued) Selected Empirical Studies Linking IT and IT-Enabled Capabilities with Firm Risk and Returns

Study	Sample	IT Variable	Dependent or Intermediate Variables	Key Findings
Oh et al. (2006)	1985–1999 event data	IT investment announcements	Cumulative abnormal return	A firm's growth prospects, uncertainty, the strategic role of IT, and discloser information are significantly related to CARs; asset specificity and uncertainty interacts negatively
Anderson et al. (2006)	Y2K investments of Fortune 1000 firms	Y2K spending	Shareholder value	Y2K spending increases firm value; the positive effect of Y2K spending is stronger for firms in transform industries
Anderson et al. (2003)	Y2K investments of Fortune 1000 firms	Y2K spending	Shareholder value	Valuation multiples on Y2K spending range from 31 to 45 for 1999 to 2002, about 3–4 times that on R&D spending; they attribute high multiples to intangible value
Brynjolfsson et al. (2002)	1987–1997 panel data	IT capital	Shareholder value	Valuation multiples on IT spending range 10–15, attribute to organizational capital
Bharadwaj et al. (1999)	1988–1993 data	IT spending	Tobin's q	IT investments have a significantly positive association with Tobin's q value

Mahoney 2006) as well as reduce coordination and procurements costs (Gurbaxani and Whang 1991; Mithas and Jones 2007; Mithas et al. 2008).

Third, IT improves existing customer relationships and helps reach new customers, sometimes involving new channels or new offerings (Mithas et al. 2005). IT systems such as customer relationship management (CRM) facilitate personalization of offerings and services through improved knowledge of customers' wants and needs, leading to better customer response, improved one-to-one marketing effectiveness (Mithas et al. 2006), and higher customer satisfaction (Ansari and Mela 2003; Babakus et al. 2004). In turn, customer satisfaction is associated with higher stock prices and shareholder values and reduced risk (Aksoy et al. 2008, 2012; Fornell et al. 2006, 2009a,b; Tuli and Bharadwaj 2009).

Overall, studies focusing on business processes are examining the activities residing in the black box of microeconomic production theory that transforms a set of inputs into outputs (Melville et al. 2004). These studies suggest that IT can be employed not only to improve individual processes but also to enable process integration across physical and organizational boundaries, thereby improving organizational performance.

72.2.3 Third Phase from Early 2000s Onward

The third phase of value research starting early 2000s began to focus on profitability and shareholder value metrics that also take into account "appropriation of value" aspect of firm performance (see Table 72.5). Previous research, using firm-level IT investment data in early 1990s (Hitt and Brynjolfsson 1996; Rai et al. 1997), failed to find a statistically significant effect of IT investments on firm profitability,

TABLE 72.4 Selected Empirical Studies Linking IT and IT-Enabled Capabilities with Intangibles

Study	Sample	IT Variable	Dependent or Intermediate Variables	Key Findings
Tafti et al. (2013)	2000–2006	IT investments	Alliance formation and alliance value	Adoption of open communication standards is associated with the formation of arms-length alliances, and modularity of IT architecture is associated with the formation of joint ventures. IT architecture flexibility enhances the value of arms-length, collaborative, and joint venture alliances. The contribution of IT flexibility to value is greater in the case of collaborative alliances than in arms-length alliances
Ravichandran et al. (2011)	1990–2005 panel data on manufacturing and service firms	IT investments	Patent counts and patent citations	IT investments have a positive and statistically significant association with patents and patent citations and the effect is stronger for the 1998–2005 period. Also, stronger effect in services than in manufacturing and higher impact on patent citations than on patent counts. Study also finds evidence that IT helps to mitigate diminishing returns to R&D
Gao and Hitt (2012)	1987–1997; 116 manufacturing firms	IT capital stock	Trademarks	More IT capital is associated with more new trademarks and retirement of existing trademarks (these signify differences among similar products) leading to shorter trademark life cycle and greater product variety
Mithas et al. (2011)	An archival data from a conglomerate	Information management capability	Customer, financial, human resources, and organizational effectiveness measures of performance	Information management capability contributes to developing other firm capabilities for customer management, process management, and performance management, which, in turn, favorably influence firm performance measures
Kleis et al. (2012)	1987–1997 data for manufacturing firms	IT investment	Innovation output (patents and citations)	A 10% increase in IT input is associated with a 1.7% increase in innovation output after accounting for R&D
Pavlou and El Sawy (2010)	Surveys of new product development managers in 2002 and 2003	IT-enabled improvisational and dynamic capabilities	Competitive advantage in new product development	While dynamic capabilities are associated with competitive advantage in moderately turbulent environments, improvisational capabilities dominate in highly turbulent environments

TABLE 72.4 (continued) Selected Empirical Studies Linking IT and IT-Enabled Capabilities with Intangibles

Study	Sample	IT Variable	Dependent or Intermediate Variables	Key Findings
Saraf et al. (2007)	Survey of business units in the high-tech and financial services industries	IS integration and IS flexibility capabilities	Knowledge sharing, process coupling, and BU performance	IS integration with channel partners and customers contributes to both knowledge sharing and process coupling with both types of enterprise partners, whereas IS flexibility is a foundational capability that indirectly contributes to value creation in interfirm relationships by enabling greater IS integration with partner firms
Ray et al. (2005)	Survey of managers in the life and health insurance industry during 2000	Shared knowledge between IT and customer service units	Customer service process performance	Shared knowledge between IT and customer service units affects customer service process performance and moderates the impacts of explicit IT resources such as the generic IT used in the process and IT spending
Mithas et al. (2005)	2001–2002 data from *InformationWeek*	Use of CRM applications	Customer satisfaction	The use of customer relationship management applications is positively associated with improved customer knowledge and improved customer satisfaction. Gains in customer knowledge are enhanced when firms share their customer-related information with their supply chain partners
Brynjolfsson et al. (2003)		Increased product variety made available through electronic markets	Consumer surplus	Increased product variety of online bookstores enhanced customer welfare by around $1 billion in the year 2000

which Dedrick et al. (2003) called the "profitability paradox" of IT. Hitt and Brynjolfsson (1996) looked for associations between IT spending and various business performance measures. Although they document IT's positive impact on output and consumer surplus, they do not find a significant positive correlation between IT spending and profitability. They proposed that the productivity benefits associated with IT use may be passed on to consumers through lower prices and not lead to greater profitability because of intense competition. However, Dedrick et al. (2003) argued that it was more likely that IT investments do actually affect profitability, but the modeling techniques and datasets used in previous studies were unable to measure the impacts. Mithas et al. (2012b,c), using archival data for the 1998–2003 period, show that IT has a positive impact on profitability and its effect is higher than that of other discretionary investments such as advertising and R&D.

Another stream of research using capital market-based measures examines whether and how firms appropriate value from their IT investments. This research generally shows that IT investments are positively associated with shareholder value and stock returns (Mithas et al. 2012a; Saunders 2010). Some of these studies indicate the need to consider risks involved with IT investments, which might explain excess returns (Dedrick et al. 2003; Dewan et al. 2007; Kim and Mithas 2011; Tanriverdi and Ruefli 2004).

TABLE 72.5 Selected Empirical Studies Linking IT and IT-Enabled Capabilities with Financial Measures and Profitability

Study	Sample	IT Variable	Dependent or Intermediate Variables	Key Findings
Mithas et al. (2012c)	1998–2003 data	IT spending	Profitability	IT has a positive impact on firm profitability; a significant portion of IT impact is accounted by IT-enabled revenue growth
Aral and Weill (2007)	1999–2002	IT investment allocations and IT capabilities	Market valuation, profitability, cost and innovation	Investments in specific IT assets explain performance differences along dimensions consistent with their strategic purpose; a system of organizational IT capabilities drive differences in firm performance
Santhanam and Hartono (2003)	1991–1994 data	IT capability	Profitability and cost	Firms with superior IT capability exhibit superior current and sustained firm performance
Bharadwaj (2000)	1991–1994 data	IT capability	Profitability and cost	Firms with high IT capability tend to outperform a control sample of firms on a variety of profit and cost-based performance measures
Rai et al. (1997)	1994 data	IT investments	Sales, return on assets (ROA), return on equity (ROE), and labor and administrative productivity	Measures of IT investments have differential effects on the various measures of business performance
Hitt and Brynjolfsson (1996)	1988–1992	IT spending	Productivity, profitability, and consumer surplus	IT increases productivity and consumer surplus, but does not increase profitability

72.3 Underlying Theories and Methodologies

While there are a number of theories from which to explain the business value of IT (see Table 72.6 for a summary of some review articles), we focus here on the create–capture value approach. Much of the productivity research focuses on the issue of value creation, while the studies relating to profitability and market value focus on appropriability of value.

Researchers use several theoretical paradigms in explaining the value creation of IT, including production economics and process-oriented models. The theory of production has been particularly useful in providing empirical specifications helping to estimate the economic impact of IT (Brynjolfsson and Hitt 1996; Lichtenberg 1995). Researchers have also employed consumer theory (Hitt and Brynjolfsson 1996), data envelopment theory (Lee and Barua 1999), and Tobin's *q* (Bharadwaj et al. 1999). Other researchers have developed process-oriented models linking IT to organizational performance in which the impact of IT on firm performance is mediated by intermediate processes (Barua et al. 1995). This approach argues that the enterprise-level impacts of IT can be measured only through a web of intermediate-level contributions.

This body of research suggests several general findings. First, IT creates value. Also, following a complementarity argument, IT infrastructure does not create value in isolation but must be a part of a business value creating process with other organizational factors including IT human capital. The effects of IT occur at many levels (Kohli and Grover 2008), and IT can be treated as an "option" that is valuable because it provides an opportunity to reap benefits if or when the need arises (Benaroch 2002). This argument endows management with flexibility to embrace and manage uncertainty using IT.

TABLE 72.6 Selected Conceptual Reviews or Theories Linking IT and IT-Enabled Capabilities with Firm Performance

Study	Theoretical Lens	IT Variable	Dependent or Intermediate Variables	Proposed Moderating Variables	Key Findings
Melville et al. (2004)	Integrative model	IT resources (technology and human)	Business processes, business process performance, organizational performance	Complementary organizational resources, industry characteristics, and trading partner resources	The high degree of complexity leads to a context-contingent set of synergistic combinations of IT and other organizational resources
Wade and Hulland (2004)	Resource-based view	IS resources (manage external relationships, market responsiveness, etc.)	Competitive advantage	Organizational factors (e.g., top management commitment to IS) and environmental factors (e.g., environmental munificence)	Only IS resources that are inimitable, nonsubstitutable, and imperfectly mobile will have a positive effect on competitive position in the longer term
Piccoli and Ives (2005)	Integrative framework	IT-dependent strategic initiatives	Sustainable competitive advantage		Identify four barriers to erosion for sustained competitive advantage: IT resources barrier, complementary resources barrier, IT project barrier, and preemption barrier. They identify the response lag drivers underpinning these barriers, as well as the process of organizational learning and asset stock accumulation by which they may be strengthened over time
Nevo and Wade (2010)	Systems theory and resource-based view	IT asset	Sustained competitive advantage, synergy, strategic potential		Greater compatibility between an IT asset and an organizational resource positively affects the extent of realized synergy

Although the previous literature focusing on IT value creation perspective provides valuable insights of IT impacts, the external environment of trading partners, industry characteristics, and sociopolitical conditions is also important, but rarely incorporated in analyses. Moreover, prior work has paid less attention to how the IT benefits are appropriated. Some researchers use game theory to examine the role of strategic interaction among competitors in IT business value capture (Belleflamme 2001). Other researchers draw from agency theory and the incomplete contracts literature (Bakos and Nault 1997).

The resource-based view (RBV) of the firm has been a popular framework in the business value of IT literature. This approach is useful in providing a robust framework for analyzing whether and how IT may be associated with competitive advantage (Bharadwaj 2000; Mithas et al. 2012c; Piccoli and Ives 2005; Powell and Dent-Micallef 1997). This body of research suggests that the IT benefits generated can be dissipated from competition. Differential firm value from IT is elusive since it can be copied and competed away, even though value can be created at the industry and economy level. RBV suggests that firms can create differential value by leveraging IT and complementarities to create resources and capabilities that are heterogeneous and imperfectly mobile.

Mithas et al. (2012c) draw on the RBV of the firm as an overarching framework and propose three reasons to explain why overall IT investments are likely to have a positive association with accounting profits. First, an explanation based on virtuous cycle argument suggests that firms that invest in IT in period 1 reap benefits and then invest more in IT in period 2. Over time, these effects become magnified, leading some firms to continue investing more in IT compared with their historical investment and that of their competitors; these firms maintain a more proactive digital strategic posture. Because of their higher investments in IT and greater opportunities to learn from occasional failures in their overall IT portfolio, the firms undergoing the virtuous cycle are also likely to become better at managing IT.

A second, learning-based explanation suggests that years of continued investments in IT and experience in managing these systems may have improved the capability of firms to leverage information and strengthen other organizational capabilities (Grover and Ramanlal 1999, 2004; Mithas et al. 2011). In support of this explanation, several empirical studies show that firms have learned how to make use of IT to improve customer satisfaction, at the same time boosting profitability through the positive effects of customer loyalty, cross-selling, and reduced marketing and selling costs (Fornell et al. 2006, 2009a; Grover and Ramanlal 1999; Mithas and Jones 2007; Mithas et al. 2005).

A third explanation, based on Kohli's (2007) work, suggests that because of a long history of firms viewing IT mainly as an automation-related investment, with a focus on cost reduction rather than revenue generation, firms may have "just about exhausted efficiency gains from IT" (p. 210). To the extent, RBV focuses on differential firm performance; if revenue growth has become a primary driver for differentiation because of exhaustion of cost-based differentiation, tracing the effect of IT on profitability through revenue growth may be more promising than through cost reduction. These three explanations (virtuous cycle, learning, and strategic posture of differentiating through revenue growth rather than through cost reduction) relate to the key tenets of RBV, which uses the notions of social complexity, erosion barriers, path dependence, and organizational learning to explain why resources create and sustain a competitive advantage (see Piccoli and Ives 2005).

Among methodologies, researchers have used quantitative and qualitative approaches to study the business value of IT. The use of longitudinal archival data and panel models has helped to strengthen claims regarding causality. At the same time, use of newer methodologies such as propensity scores has been particularly useful to view causality from a counterfactual perspective (Chang and Gurbaxani 2012; Mithas and Krishnan 2009), complementing other approaches based on explained variance (as in regression), explained covariance (as in structural equation models, such as LISREL), prediction (as in partial least squares), or a comparison of performance at time t with some prior time (t–1) (as in "before-and-after" study designs). While large sample studies will continue to be important and availability of even more granular data will provide new opportunities to explore causal mechanisms more closely, we also call for detailed longitudinal case studies of firms (e.g., Mandviwalla and Palmer 2008; Marchand 2002). Sometimes these detailed case studies can provide very useful insights to guide further quantitative research, beyond their value in teaching.

72.4 Impact on Practice

Questions about IT value have forced CIOs to look for more opportunities to enhance revenue as opposed to applications that cut costs. The impact of $1 million additional profits, whether through revenue or through savings, is exactly the same. But contributing to revenue may lead to more

sustainable competitive advantage (Mithas et al. 2012b) and may allow CIOs and other executives to leverage newer opportunities enabled by IT, which may not be obvious if they were to narrowly focus on reductions in IT costs alone. Indeed, if marginal increase in IT investments is outweighed by reductions in non-IT costs, then firms are better off increasing their IT investments as some firms have realized (Glazer 2012; Han and Mithas 2013; Worthen 2012). It may also be that cost savings are often not tracked, and when they are, they frequently prove to be less than promised when a system was approved.

Managers with a focus on revenue generation will look for way to support customers and a firm's sales efforts. For example, a firm might implement Salesforce.com or some other CRM system to leverage the efforts of its sales force. Getting a new drug through trials and the approval process is critical for revenue in the pharmaceuticals industry so IT can contribute to earlier revenue recognition with a system to manage and expedite clinical trials. The Internet and the ability to reach customers easily provides a platform for efforts to improve revenues in a variety of ways, from CRM systems to order entry applications that make it easier to do business with the firm.

Since the Internet became available for profit making use in 1995, IT has become an integral part of many business models. Firms like Google, eBay, Amazon, Facebook, Twitter, and others rely on technology to function. Without IT, they could not exist. What is the value of information technology to these firms? Consider the case of Amazon in which the technology enabled it to create and execute a business model for retail sales over the Internet. As a result of its expertise in building and operating infrastructure, Amazon has a booming business of selling cloud computing services to companies like Netflix that do not want to develop their own technology infrastructure. Is there any way to value technology in these cases? Is technology equal to the value of the firm or its annual sales?

Table 72.7 lists the sales and market capitalization of a number of firms with business models intertwined with the Internet. All of these firms have created value through technology. Google, Amazon, and eBay are publicly traded companies and are profitable. Can we attribute their profitability to technology? The answer

TABLE 72.7 When IT and Business Morph into Each Other

Firm	2011 Sales (All Values Are in Millions US$)	2011 Market Cap (All Values Are in Millions US$)	Remarks
1. Amazon	48,077	82,467	Sales—Period ended December 31, 2011
2. Netflix	3,204	5,789	Sales—Period ended December 31, 2011
3. Facebook[a]	3,700[b]	65,000–100,000[b]	*Source*: *USA Today* (Swartz, Martin, and Krantz 2012) Date: Sales—Period ended December 31, 2011
4. Twitter[a]	139[c]	7,700[d]	*Source*: *eMarketer* (Fredricksen 2011) and *Reuters* (Reuters 2011) Date: Sales—2011
5. Google	37,905	199,077	Sales—Period ended December 31, 2011
6. eBay	11,651	48,246	Sales—Period ended December 31, 2011
7. Groupon	1,624	10,835	Sales—Period ended December 31, 2011
8. Apple	108,249	544,140	Sales—Period ended September 24, 2011

Notes: Annual sales information was collected from Bloomberg. Market capitalization information is as of March 14, 2012, and this data was collected from Bloomberg.

[a] Facebook and Twitter Sales and Market Cap are based on news stories because these firms are yet to trade at the time of writing of this article.

[b] From http://www.usatoday.com/tech/news/story/2012-02-01/facebook-ipo/52921528/1

[c] From http://www.emarketer.com/PressRelease.aspx?R=1008617

[d] From http://www.reuters.com/article/2011/03/04/us-twitter-idUSTRE7221JL20110304

is no because it is the application of technology merged with other business processes that account for their success. Amazon is extremely good at logistics and fulfilling orders. Google has captured the market for search advertising. For these firms, technology is such an important part of their existence that managers simply assume that it will be there like their office or phone. Under these conditions, does it make any sense to try and put a value on IT, or should the focus be on how to manage the technology effectively?

72.5 Research Issues and New Frontiers

We identify several directions for further research. First, the rising use of social networks by businesses raises questions to assess how these networks create value for firms by enabling knowledge exchanges within the firm and with external customers, suppliers, and business partners. Social network data can be very rich and complex with several layers of nesting. For example, one can view individual messages nested in threads, which, in turn, are often nested in forums. Making sense of such nesting can be very complex because messages can also be analyzed at the level of individual contributors, firms, and countries. We expect new methodological innovations and significant extensions of hierarchical linear models to analyze such datasets to generate useful insights.

Second, although we have made significant progress by learning from large sample archival datasets, there is a need for detailed studies of information and technology use inside large and evolving born-digital global firms to understand how firms scale up their information management capabilities to cope with more turbulent and uncertain industry environment.

Third, researchers have paid significant attention to understanding the impact of IT investments, and there have been studies and conceptual frameworks that study IT strategies and IT governance. However, there remains a need to study the joint effects of IT strategies and IT investments on firm performance. In particular, we need to study the interaction between IT investments and ambidextrous strategies (such as the ones that focus on multiple objectives such as revenue growth and cost reduction at the same time) and implications for firm performance (Mithas and Rust 2009). To the extent IT strategies of firms are also shaped by their competitive environment, understanding how competitive environment affects the influence of strategic posture of a firm on its digital business strategy is an important area of research (Mithas et al. 2013).

Fourth, as society digitizes and economies become more globally interconnected, firms are increasingly making use of globally dispersed resources to manage their IT assets. In this context, the role of IT professionals and firm's choice of how to provide IT services using internal IT labor and outsourced IT labor can be investigated by looking at how such choices influence firms' ability to innovate and stay entrepreneurial. We also need a better understanding of how outsourcing service providers create value for firms by helping to reduce non-IT costs and providing a service differentiation advantage (Han and Mithas 2013; Ramasubbu et al. 2008). The role of foreign-born immigrant workers and that of IT professionals located abroad in complementing native workers in firms' profit functions is a fruitful area of research because of significant policy debates and implications that surround movement of people across country borders (Lucas and Mithas 2011; Mithas and Han 2012; Mithas and Lucas 2010).

Fifth, while IT-enabled transformations are spreading across industries, we still do not have adequate theories and methods to investigate such innovations systematically. Although case examples and anecdotal accounts have enriched our understanding of sustaining versus disruptive innovations, more rigorous conceptualizations of core concepts and empirical testing of assertions based on case examples are necessary to draw valid conclusions.

Sixth, because of rising concerns related to climate change there is a need to study how IT can contribute to reducing carbon emissions through more sustainable business operations. This will require broadening the dependent variables for business value of IT research beyond customer satisfaction, profitability, shareholder value, and bondholder value.

Finally, increasing digitization of the economy is accompanied by a rise in services. However, as noted by the prominent economist William Baumol, the unit cost of services increases over time because

productivity growth in services generally lags well behind productivity growth in manufacturing, but real wages grow at about the same rate in the two sectors. This phenomenon of growth in costs of services relative to the rate of inflation, which has come to be known as “Baumol’s cost disease” (see Baumol 1993, 1996; Baumol and Blackman 1983), afflicts many services such as healthcare, education, auto repair, auto insurance, legal services, restaurant services, and public services. For example, the cost of higher education at private colleges in the United States in 2010 was ~2.5 times than in 1982 in inflation-adjusted dollars (Hacker and Dreifus 2010). Similar trends have also been noted in healthcare, which has witnessed significant increase in costs in excess of inflation (Bohmer and Knoop 2006; Reid 2009). A key question in this context is whether and what types of IT resources can help firms, universities, and governments to bend the cost curve in services. At the same time, the role of IT and e-government services to improve access, transparency, quality of services, and citizen satisfaction needs further investigation. This is particularly the case in emerging economies where governments are often viewed with suspicion and corruption in government services is taken for granted (Gupta et al. 2012; Morgeson and Mithas 2009). There is much that organizations can learn from experience of others in different country settings. Therefore, comparative studies across countries can be particularly helpful.

72.6 Conclusion

Our goal in this chapter was to review the business value of information technology literature in last 50 years since the origin of the academic discipline of information systems in business schools in the 1960s. We identified key milestones, reviewed what we know, and suggested some promising directions for future research. The last 40 years have brought many new insights, theories, and methods to answer the question of how IT creates value and how some of that value can be appropriated by those who invest in IT. However, the changing nature of IT and concomitant changes in the economy due to globalization, the rise of emerging economies such as China and India, concerns about sustainability of our planet, and rising costs of essential services such as healthcare and education suggest that organizations continue to be challenged to define and create new metrics and ways of measuring IT value in the next 40 years. The possibilities for new research opportunities and finding creative solutions to societal and organizational problems using IT are immense and that should be exciting for researchers and practitioners alike.

Acknowledgment

We thank Keongtae Kim for assisting with this research.

Computer Science

Computing Handbook, Third Edition: Information Systems and Information Technology demonstrates the richness and breadth of the IS and IT disciplines. The second volume of this popular handbook explores their close links to the practice of using, managing, and developing IT-based solutions to advance the goals of modern organizational environments. Established leading experts and influential young researchers present introductions to the current status and future directions of research and give in-depth perspectives on the contributions of academic research to the practice of IS and IT development, use, and management.

Like the first volume, this second volume describes what occurs in research laboratories, educational institutions, and public and private organizations to advance the effective development and use of computers and computing in today's world. Research-level survey articles provide deep insights into the computing discipline, enabling readers to understand the principles and practices that drive computing education, research, and development in the twenty-first century.

Features

- Aligns with the undergraduate curriculum models developed by the Association for Computing Machinery (ACM) and the Association for Information Systems (AIS)
- Discusses the nature and identity of the IS and IT disciplines
- Examines current topics in IS and IT, including data and information management, human–computer interaction, management of IT capabilities, and the role of IT in organizations and markets
